
Demonstrating the Set_Report Request With a PS/2[®] to USB Keyboard Translator Example

*Author: Reston Condit
Microchip Technology Inc.*

INTRODUCTION

This Technical Brief details the translation of a PS/2[®] keyboard to a USB keyboard using the PIC16C745/765. Although this is a fairly simple application for the PIC16C745/765, it accomplishes the intended purpose of this brief: to provide an in-depth look at the Set_Report request.

Note: This Technical Brief is the third in a series of five technical briefs. This series is meant to familiarize developers with USB. For the best understanding of USB, read the briefs in order: TB054, TB055, TB056, TB057 and TB058.

The Set_Report Request

The Set_Report request is a HID specific command. It was the only provision in Version 1.0 of the USB specification that could send data from the host to a peripheral. This later changed with Version 1.1 and the introduction of the interrupt OUT transfer. All low-speed devices created before the introduction of Version 1.1 had to use the Set_Report request for host-to-device communication. The limitation of this is that Set_Report communicates over Endpoint 0 (EP0). Endpoint 0 is the control endpoint. In other words, EP0 is the avenue through which the device and host send each other commands, so any outputted data from the host has to share bandwidth with administrative commands sent back and forth between the host and the device. Developers wanted a way to create a dedicated OUT endpoint with one or both of the endpoints available to them, EP1 and EP2. As a result, Version 1.1 of the USB specification included a provision for the interrupt OUT transfer.

Note: IN and OUT are with respect to the host.

There are many instances where the Set_Report request is useful in today's USB devices. In devices where the maximum amount of bandwidth is needed for device-to-host transactions, both EP1 and EP2 can be set as IN endpoints. If the same device must receive occasional data packets from the host, it is better to use the Set_Report request to send that data from the host to the device than to change either EP1 or EP2 to an OUT endpoint. The keyboard is an example of a peripheral in which the host occasionally sends it data, namely, the status of the keyboard LEDs (Caps Lock, Num Lock and Scroll Lock LEDs are the most common LEDs). This data is sent from the host to the device with the Set_Report request only when the user presses one of the corresponding keys for these LEDs (i.e., the Caps Lock key).

Note: The Get_Report request, not talked about in this brief, is similar to Set_Report, only it is used for sending data from the device-to-host via Endpoint 0.

Descriptors

Figure 1 shows the USB keyboard report descriptor. There are two Output items in this report descriptor. These items describe a byte of data that will be sent from the host to the device comprised of five LED status bits and three bits of padding. Because this report descriptor is associated with an IN endpoint (specified by the endpoint descriptor), the host knows all Output items describe data that will be sent to the device via a Set_Report. The remainder of the descriptor describes the format that data will be sent from the keyboard to the host. The output data should be ignored when trying to envision what the device-to-host report format looks like. See Figure 2 for the USB keyboard-to-host data format.

PS/2 KEYBOARD REPORT FORMAT

The PS/2 keyboard data report format is summarized for every key in Appendix A. Make codes are the byte or bytes that the PS/2 keyboard sends to the host when a certain key is pressed. Break codes are the bytes that the PS/2 keyboard sends when the user releases a key. If the user does not release a specific key for several hundreds of milliseconds, the make code will be sent repeatedly until the user releases the key. At this point, the break code is sent.

INTERRUPT ROUTINE

The translator firmware is entirely interrupt-driven (with the exception of sending the data via USB to the host). An interrupt is generated when the PS/2 Start bit is received, at which time the firmware will begin its receive routine. In addition to this interrupt, every 683 μ s a timer overflow interrupts the main program and implements one state of the keyboard state machine. This state machine handles sending bytes to (and translating bytes received from) the PS/2 device automatically. All of this is done in the background while the main program runs in the foreground. The only operation that the main program implements is sending keyboard data to the PC via USB.

TRANSLATION TO USB

Incoming PS/2 keyboard data can be one to eight bytes in length, depending on the button that is pressed. No pattern or mathematical expression can be used to convert incoming PS/2 data to a USB key code. USB key codes are one byte in length. There is one USB key code for every key on the keyboard. A lengthy look-up table, found in file `table_kb.asm`, translates from PS/2 to USB key codes. The USB key codes are listed in Section 9 of the USB HID Usage Tables (see References).

MAKING THE KEYBOARD LEDS WORK

The state of the LEDs on a USB keyboard is passed from the host to the device via the `Set_Report` request. The `Set_Report` request transfers the data specified by the Output items in the report descriptor listed in Figure 1. The data consists of one byte, in which the first five bits represent the LED status. This data is sent from the host to the PICmicro® MCU only when the host receives a key code that modifies the state of a LED, such as the CAPS LOCK key code.

The microcontroller firmware services the `Set_Report` request. `Set_Report` requests are serviced in the `HidSetReport` routine. `HidSetReport` copies the `Set_Report` data from the EP0 OUT buffer to the EP1 OUT buffer. This is how the default USB support firmware treats a `Set_Report` request -- it makes a `Set_Report` look like an interrupt EP1 OUT transfer. A developer using the support firmware needs only to decide how to service the interrupt EP1 OUT transfer. For the keyboard example, this trick was not utilized. The keyboard state machine simply reads the EP0 OUT buffer to find out the LED states. Special Function Register (SFR) `BD00AL` contains the address of this buffer. `BD00BC`, also a Special Function Register, specifies the number of bytes received. The LED status report comprises one byte so only the first byte of the buffer needs to be read in order to determine the state of the keyboard LEDs. Once the status is known, this information is relayed to the keyboard via PS/2.

CONCLUSION

The `Set_Report` request is useful in low-speed USB applications where the maximum amount of bandwidth available is required for IN transactions, yet it is necessary to occasionally support OUT transactions. In addition to providing an example of the `Set_Report` request, the firmware included with this technical brief provides ready-made routines for communicating via PS/2.

MEMORY USAGE

In the PIC16C765, the following memory was used

Data Memory: 50 Bytes
Program Memory: 2.1K Bytes

NOTES:

Note the following details of the code protection feature on Microchip devices:

- Microchip products meet the specification contained in their particular Microchip Data Sheet.
- Microchip believes that its family of products is one of the most secure families of its kind on the market today, when used in the intended manner and under normal conditions.
- There are dishonest and possibly illegal methods used to breach the code protection feature. All of these methods, to our knowledge, require using the Microchip products in a manner outside the operating specifications contained in Microchip's Data Sheets. Most likely, the person doing so is engaged in theft of intellectual property.
- Microchip is willing to work with the customer who is concerned about the integrity of their code.
- Neither Microchip nor any other semiconductor manufacturer can guarantee the security of their code. Code protection does not mean that we are guaranteeing the product as "unbreakable."

Code protection is constantly evolving. We at Microchip are committed to continuously improving the code protection features of our products. Attempts to break Microchip's code protection feature may be a violation of the Digital Millennium Copyright Act. If such acts allow unauthorized access to your software or other copyrighted work, you may have a right to sue for relief under that Act.

Information contained in this publication regarding device applications and the like is intended through suggestion only and may be superseded by updates. It is your responsibility to ensure that your application meets with your specifications. No representation or warranty is given and no liability is assumed by Microchip Technology Incorporated with respect to the accuracy or use of such information, or infringement of patents or other intellectual property rights arising from such use or otherwise. Use of Microchip's products as critical components in life support systems is not authorized except with express written approval by Microchip. No licenses are conveyed, implicitly or otherwise, under any intellectual property rights.

QUALITY MANAGEMENT SYSTEM
CERTIFIED BY DNV
== ISO/TS 16949:2002 ==

Microchip received ISO/TS-16949:2002 quality system certification for its worldwide headquarters, design and wafer fabrication facilities in Chandler and Tempe, Arizona and Mountain View, California in October 2003. The Company's quality system processes and procedures are for its PICmicro® 8-bit MCUs, KEELoQ® code hopping devices, Serial EEPROMs, microperipherals, nonvolatile memory and analog products. In addition, Microchip's quality system for the design and manufacture of development systems is ISO 9001:2000 certified.
