INTRODUCTION

This application note presents a LIN slave driver for the PIC18F1320 using the Enhanced USART (EAUSART) module. There are many details to this firmware design; however, this application note focuses mainly on how to set up and use the driver. Therefore, the LIN system designer should be able to get an application running on LIN quickly without spending a significant amount of time on the details of LIN.

Many details about the firmware design are provided at the end of this document for the curious designer who wants to learn a little more about LIN and this driver implementation.

The information in this application note is presented with the assumption that the reader is familiar with LIN specification v1.2, the most current specification available at the time this document was written. Therefore, not all details about LIN are discussed. Refer to the References section of this document for additional information.

DRIVER RESOURCES

The first question that must be asked is: “Will this driver work for my application?” The next few sections can help those who would like to know the answer to this question and quickly decide whether this is the appropriate driver implementation or device for their application. The important elements that have significant weight on this decision include available process time, resource usage, and bit rate performance.

Process Time

Available process time is dictated predomnately by bit rate, clock frequency, and code execution. Fortunately, the driver implementation for the PIC18F1320 uses the Enhanced USART module. This hardware resource puts more processing in hardware and less demand for firmware; therefore, the average available process time is relatively high. Figure 1 shows the approximate average available process time for Fosc equal to 8 MHz. (This time evaluation includes only the operation of the driver; Timer0 process handling is not included.)

Resource Usage

The resource usage is minimal on the PIC18F1320. Only two hardware modules are used. The EAUSART module is used for communications, and the Timer0 module is used for bus and frame timing.

Similarly, the driver consumes only a small portion of the memory resources. The driver alone (not including the application and event tables) uses 215 words of program memory and 14 bytes of data memory.

Bit Rate

The driver is designed to achieve up to the maximum bit rate defined by the LIN specification, 20000 bps, using the internal 8 MHz clock source. Figure 2 shows the recommended operating regions.

Summary

The LIN slave driver takes advantage of the Enhanced USART module to handle most of the otherwise demanding processing, so process time is of little concern for most applications. Timer0 is the only other resource, and it interrupts at the bit rate. Therefore, the driver can run virtually transparent in the background without significant interference to the application. This means there is plenty of time for firmware dominant applications. In addition, the PIC18F1320 has additional hardware features, such as PWM, CCP, A/D, and multiple timers.

Since most of the resources, including process time, are available, this driver is well suited for high demand, high process time applications. Some examples include complex motor controls, instrumentation, multiple feedback applications, and possibly, low to moderate speed engine controls.
SETTING UP THE DRIVER

Now that the decision has been made to use this driver, it is time to set up the firmware and start building an application. For an example, a complete application provided in the appendixes, is built together with the LIN driver. The code provided is actually a simple, yet functional application, demonstrating a generic LIN I/O node.

Here are the basic steps required to set up your project:

1. Set up a project in MPLAB® IDE. Make sure you have the important driver files included in your project:
   - lin.asm
   - timer.asm
   - linevent.asm

2. Include a main entry point in your project, main.asm. Edit this file as required for the application. Make sure that the interrupt is set up correctly, and initialize the driver. Also ensure any external symbols are included.

3. Edit linevent.asm to respond to the appropriate IDs. This could be a table or some simple compare logic. Be certain to include any externally defined symbols.

4. Add any additional application related modules. The example uses memio.asm for application related functions related to specific IDs.

5. Edit the lin.def file to setup the compile time definitions of the driver. The definitions determine how the driver functions.

The Project

The first step is to set up the project in MPLAB IDE. Figure 3 shows an example of what the project setup should look like. The following files are required for the LIN driver to operate:

- lin.lkr - linker script file
- main.asm - the main entry point into the program
- timer.asm - Timer0 control
- lin.asm - the LIN driver
- linevent.asm - LIN event handling table

Any additional files are defined by the system designer for the specific application. For example, Figure 3 lists an additional project file, memio.asm. This particular file is used for handling I/O operations on RAM in the example application. Other files could be added and executed through the main module, main.asm, and the event handler.

FIGURE 3: PROJECT SETUP
The Main Module

The main.asm module contains the entry point into the program, which is where the driver, hardware, and variables should be initialized. To initialize the driver, call the _init_hw function (refer to Appendix B for an example).

Within the main module is the interrupt vector. This is where the driver function, _txrx_driver, must be called as shown in Example 1. Within the function, the interrupt flag for the EAUSART module is automatically checked.

The timer function is also placed in the interrupt. The example firmware uses Timer0 for bit timing; however, the LIN designer can choose any timer and write the appropriate code. Again, Example 1 shows the placement within the interrupt. Refer to Appendix B for details about the UpdateTimer function.

Definitions

There are a few compile time definitions, all of them located in lin.def, that are used to set up the system. Table 1 lists and describes these definitions. The definitions are also listed in Appendix A.

</tbody>
</table>
LIN Events
LIN event functions are where the ID is decoded to determine what to do next, transmit, receive, and how much. The designer should edit or modify the event function to handle specific LIN IDs (refer to Appendix B for an example). One possibility is to set up a jump table, which is useful for applications that require responding to multiple IDs. Another option is to set up some simple compare logic.

Application Modules
The application firmware must be developed somewhere in the project. The firmware can be in main or in separate modules; however, from a functional perspective it does not matter. The example firmware uses a separate ID module for individual handling of application associated functions. The most important part to remember is to include all of the external symbols that are used. The symbols used by the driver are in lin.inc, which should be included in every application module.

The modules that are set up in the example have two parts. One part is the handler for the ID Event. This small function is used to set up the driver to handle the data. Any other functions are part of the application.

USING THE DRIVER
After setting up a project with the LIN driver’s necessary files, it is time to start using the driver. This section presents pertinent information about using the driver. The important information addressed is:

- Handling finish flags
- Handling error flags
- State flags within the driver
- LIN ID events
- Bus wake-up

The source code provided is a simple example on using the LIN driver in an application.

Finish Flags
There are two flags that indicate when the driver has successfully transmitted or received data. The receive flag is set when data has been received without error. This flag must be cleared by the user after it is handled. Likewise, the transmit flag indicates when data has been successfully transmitted without error. The transmit flag must also be cleared by the user after it is handled. Refer to Appendix A for the list of flags and their definitions.

Error Flags
Certain error flags are set when expected conditions are not met. For example, if the slave failed to generate bit timing within the defined range, a sync error flag will get set in the driver.

Errors are considered fatal until they are handled and cleared. Thus, if the error is never cleared, then the driver will ignore incoming data.

The following code, shown in Example 2, demonstrates how to handle errors within the main program loop. This example only shows a response to a bus time-out error. This same concept can be applied to other types of errors.

EXAMPLE 2: ERROR HANDLING

```
MOVF LIN_STATUS_FLAGS, W ;Errors?
BNZ LinErrorHandler

LinErrorHandler
BTFSC LE_BTO ; Was the
   BRA PutToSleep ; bus time exceeded?
CLRF LIN_STATUS_FLAGS ; Reset
BRA Main ; errors
```

Notice that the errors are all contained within a single register. So the LIN_STATUS_FLAGS register can be checked for zero to determine if any errors did occur.

Driver State Flags
The LIN driver uses state flags to remember where it is between received bytes. After a byte is received, the driver uses these flags to decide what is the next unexecuted state, then jumps to that state. One very useful flag is the LS_BUSY flag. This bit indicates when the driver is active on the bus, so this flag could be used in applications that synchronize to the communications on the bus. The other flags indicate what has been received and what state the bus is in. Refer to Appendix A for descriptions of the state flags.

ID Events and Functions
For each ID there is an event function. The event function is required to tell the driver how to respond to the data following the ID. For example, does the driver need to prepare to receive or transmit data. Also, how much data is expected to be received or transmitted.

For successful operation, three variables must be initialized: a pointer to data memory, frame time, and the count, as shown in Example 3.
EXAMPLE 3: VARIABLE INITIALIZATION

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MOVLW High ID00_BUFF; Set the pointer</td>
<td></td>
</tr>
<tr>
<td>MOVWF LIN_POINTER</td>
<td></td>
</tr>
<tr>
<td>MOVLW Low ID00_BUFF</td>
<td></td>
</tr>
<tr>
<td>MOVWF LIN_POINTER + 1</td>
<td></td>
</tr>
<tr>
<td>MOVLW d'43' ; Adjust the frame time</td>
<td></td>
</tr>
<tr>
<td>ADDWF FRAME_TIME, F</td>
<td></td>
</tr>
<tr>
<td>MOVLW 0x02 ; Setup the data count</td>
<td></td>
</tr>
<tr>
<td>MOVWF LIN_COUNT</td>
<td></td>
</tr>
<tr>
<td>RETLW 0x00 ; Read</td>
<td></td>
</tr>
</tbody>
</table>

The pointer to memory tells the driver where to store data or where to retrieve data. The frame time is the adjusted time based on the amount of bytes to expect. Typically, the frame time register will already have time left over from the header, so time should be added to the register. For two bytes, this would be an additional \((30 + 1) \times 1.4\) bit times, or 43; the value 30 is the total bits of data, START bits, and STOP bits, plus the checksum bits. The counter simply tells the driver how much data to operate on. Note that the count must always be initialized to something greater than zero for the driver to function properly.

Waking the Bus

A LIN bus wake-up function, _l_tx_wakeup_, is provided for applications that need the ability to wake the bus up. Calling this function will broadcast the wake-up request character.

IMPLEMENTATION

There are four functions found in the associated example firmware that control the operation of the LIN interface:

- LIN Transmit/Receive Driver
- LIN Timekeeper
- LIN Hardware Initialization
- LIN Wake-up

The Driver

The Enhanced USART module is the key element used for LIN communications. Using the Enhanced USART module as the serial engine for LIN has certain advantages. One particular advantage is it puts serial control in the hardware rather than in the software. Thus, miscellaneous processing can be performed while data is being transmitted or received. With this in mind, the Slave Node LIN Protocol Driver is designed to run in the background, basically as a daemon.

The driver is interrupt driven via the EAUSART receive interrupt. Because of the physical feedback nature of the LIN bus (Figure 4), a EAUSART receive interrupt will occur regardless of transmit or receive operations. Bit flags are used to retain information about various states within the driver between interrupts. In addition, status flags are maintained to indicate errors during transmit or receive operations.

FIGURE 4: SIMPLIFIED LIN TRANSCEIVER

STATES AND STATE FLAGS

The LIN driver uses state flags to remember where it is between interrupts. When an interrupt occurs, the driver uses these flags to decide what is the next unexecuted state, then jumps to that state. Figure 5 and Figure 6 outline the program flow through the different states. The state flags are listed in Table A-4 of Appendix A.

SYNCHRONIZATION

The EAUSART module has an advanced feature; it has the ability to automatically detect the bit rate. While receiving the serial data 0x55 (character 'U'), the clock cycles are counted to determine what the incoming bit rate is. This hardware feature is used to perform synchronization.

TX/RX TABLE

A transmit/receive table is provided to determine how to handle data after the node has successfully received the ID byte. The table returns information to the driver about data size and direction. The coding of this table must be defined for the application.
STATUS FLAGS

Within various states, status flags may be set depending on certain conditions. For example, if the slave receives a corrupted checksum, then a checksum error is indicated through a status flag. Unlike state flags, status flags are not reset automatically. Status flags are left for the LIN system designer to act upon within the higher levels of the firmware.

LIN Timers

The LIN specification identifies maximum frame times and bus IDLE times. For this reason, a timekeeping function is implemented. The timekeeping function works together with the driver and the transmit and receive functions. Essentially, the driver and the transmit and receive functions update the appropriate time, bus and frame time, when called. Figure 5 and Figure 7 show where the timers are updated.

The timekeeping function is implemented independent of a timing source. All that is required is that the time keeping function be called at least once per bit time. The example firmware provided (see Appendix B) uses the Timer0 module; however, it is possible to use any other time source. Some examples include using Timer1, Timer2, or even an external time source into an interrupt pin.

Hardware Initialization

An initialization function is provided to set up the necessary hardware settings, basically the EAUSART. Also, the state and status flags are all cleared. Flags related to hardware interrupts and timers are not modified.

Wake-up

The only time the slave can transmit to the bus without a request is when the bus is sleeping. Basically, any slave can transmit a wake-up signal. For this reason, a wake-up function is defined, and it sends a wake-up signal when called.

DETERMINING OPERATING REGION

It is important to understand the relationship between bit rate and clock frequency when designing a slave node in a LIN network. This section focuses on developing this understanding based on the LIN specification. It is assumed that the physical limits defined in the LIN specification are reasonable and accurate; therefore, this section merely uses the defined physical limits and does not present any analysis of the limits defined for the physical interface to the LIN bus. Essentially, the focus of this section is to analyze the firmware and its performance based on the defined conditions in LIN Protocol Specification v1.2.

General Information

Some general information used throughout the analysis is provided here.

DATA RATE VS. SAMPLING RATE

There are essentially two rates to compare, the incoming data rate and the sampling rate. The slave node only has control of the sampling rate. Therefore, for this discussion, the logical choice for a reference is the incoming data rate, \( B_I \). The equations that follow assume \( B_I \) is the ideal data rate of the system.

BASE EQUATIONS

The frequency/bit rate relationship of the EAUSART module is defined as:

\[
X = \frac{F_{osc}}{4B} - 1
\]

The value \( X \) represents the 16-bit value loaded in the SPBRG register. A more useful form of the equation is as follows:

\[
B = \frac{F_{osc}}{4(X+1)}
\]

This shows bit rate as a function of frequency and \( X \).

SAMPLING

The EAUSART does a three sample majority detect of the incoming signal, shown in Figure 8. Analytically, this looks like a single sample at the center with some noise immunity, and this is assumed in the analysis.
RELATING CLOCK FREQUENCY ERROR TO BIT ERROR

The LIN Protocol Specification v1.2 refers to clock frequency error rather than bit error. Because of this, technically, the LIN system designer must design the system with like clock sources, which is rather impractical. It is more feasible to have clock sources designed for the individual needs of the node. For this reason, all of the equations in this section refer to bit error rather than frequency error. The following equation relates frequency error to bit rate error.

\[
\frac{1}{1 + F_E} - 1 = B
\]

For very low clock frequency errors, the bit rate error can be approximated by:

\[
-E_F \approx E_B
\]

Thus, a ±2% frequency error is nearly the same bit rate error.

Acceptable Bit Rate Error

The LIN Protocol Specification v1.2 allows for a ±2% error for master - slave communications. This section evaluates this tolerance based on specified worst case conditions (slew rate, voltage, and threshold) and the EAUSART module design.

IDEAL SAMPLING WINDOW

It is relatively easy to see the maximum allowed error in the ideal situation. Ideal is meant by infinite slew rate with a purely symmetrical signal, like the signal shown in Figure 9.

![Figure 9: Ideal Window](image)

If the data sampling is greater or less than half of one bit time, \( T_E \), over nine bits, the last bit in one byte will be interpreted incorrectly. Figure 10 depicts how data may be misinterpreted because the incoming bit rate is misaligned with the sampling bit rate.

![Figure 10: Data vs. Sampling](image)

The two equations that give the maximum and minimum bit rates based on time shifting, \( T_E = \pm 1/(2B) \), are:

\[
\frac{1}{B} \cdot \frac{T_E}{9} = \frac{1}{B_{max}} \quad \text{and} \quad \frac{1}{B} \cdot \frac{T_E}{9} = \frac{1}{B_{min}}
\]

SHORTENED WINDOW DUE TO SLEW RATE

Although the ideal sampling window may be a useful approximation at very low bit rates, slew rate and threshold must be accounted for at higher rates. Thus, the ideal analysis serves as a base for more realistic analysis.

The LIN specification defines a tolerable slew rate range and threshold. The worst case is the minimum slew rate at the maximum voltage, 1 V/µs and 18V according to LIN Protocol Specification v1.2. The threshold is above 60% and below 40% for valid data. Figure 11 shows the basic measurements.

![Figure 11: Adjusted Bit Time Error](image)

Taking the difference of the ideal maximum time and the slight adjustment due to specified operating conditions yields the following equation:

\[
T_{EI} - T_{ES} = \frac{1}{2B} \cdot \frac{(0.5V - 0.4V)}{(dV)/(dt)_{min}} = T_E
\]

Thus, \( T_E \) is slightly smaller than the ideal case. The minimum and maximum equations in the previous section yield a slightly narrower range for bit rate.
OFFSET DUE TO SLEW RATE

Not only does the slew rate and thresholds contribute to a slightly smaller window, they affect offset of all samples after the first synchronous edge, the START bit.

An offset affects the symmetry of the sampling window rather than the range. Figure 12 shows how this offset favors a negative bit rate error more than a positive bit rate error.

FIGURE 12: OFFSET FROM START EDGE DUE TO SLEW RATE AND THRESHOLD

OFFSET DUE TO SAMPLING ERROR

Sampling error of the START edge is very similar to the slew rate offset described above. The design of the EAUSART module dictates what the magnitude of this offset is. In this case, the error is simply one cycle of the clock. It is added to the minimum and maximum bit rate equations:

\[
\frac{1}{9F_{OSC}} + \frac{T_{ES}}{9} + \frac{1}{B} + \frac{T_E}{9} = \frac{1}{B_{min}}
\]

and

\[
\frac{1}{9F_{OSC}} + \frac{T_{ES}}{9} + \frac{1}{B} - \frac{T_E}{9} = \frac{1}{B_{max}}
\]

OFFSET DUE TO CIRCUIT DELAY

Offsets related to circuit conditions also affect the minimum and maximum error. Since this application note does not describe the physical interface, hardware delays are ignored in this analysis.

Minimum SPBRG Value

Given a finite bit rate error range and finite control of the bit rate, this leads to areas where the slave cannot operate. These are basically gaps where the error is outside the defined bit rate error range for a particular SPBRG value. This section provides the mathematical basis for these gaps. The equations developed in this section are provided to help the LIN designer build a robust network.

FREQUENCY RANGE

The following equation determines the clock frequency as a function of SPBRG, bit rate, and oscillator error.

\[
F_{OSC} = (E_B + 1)(X + 1)(4)(B)
\]

OVERLAPPING OPERATION

For most SPBRG values, operating range overlaps each other from one SPBRG to the next. Therefore, the slave will communicate with the master for most of the common conditions. Except for a particular error range and some clock frequencies, it is possible to never have a valid SPBRG value.
To approach this problem, the maximum frequency for a particular SPBRG value must be compared to the minimum frequency of the next SPBRG. Where they are equal is the border between continuous and discontinuous operation for any given input frequency:

\[(E_{BH} + 1)(X)(4)(B) = (E_{BL} + 1)(X + 1)(4)(B)\]

Solving this equation yields:

\[X_{low} = \frac{(E_{BL} + 1)}{(E_{BH} + 1) - (E_{BL} + 1)}\]

Therefore, for any given frequency and a defined error, a good SPBRG value will always be above \(X_{low}\). Of course, the frequency and baud rate must be selected such that SPBRG is less than or equal to 65535, the largest value supported by SPBRG. For example, for a 2% error, the lowest SPBRG value before certain clock frequencies become a problem is 25. If the theoretical minimum and maximum are used, about ±5% from the previous sections, then a SPBRG value below 10 is a problem. Therefore, for master - slave communications, a SPBRG value above 10 will work in an ideal system. However, to be within the specification, the SPBRG value should be above 25.

Summary of Operating Regions

Figure 2 summarizes the various operating regions based on the typical device specifications and information provided. The LIN designer should consult the graph in Figure 2 to find the best operating region for the application.

MEMORY USAGE

The example source code, which includes the driver and a small application program, consumes 21% of program memory and 13% of the available data memory of the PIC18F1320.

APPENDIX B: SOURCE CODE

Due to size considerations, the complete source code for this application note is not included in the text. A complete version of the source code, with all required support files, is available for download as a Zip archive from the Microchip web site, at:

www.microchip.com
Information contained in this publication regarding device applications and the like is intended through suggestion only and may be superseded by updates. It is your responsibility to ensure that your application meets your specifications. No representation or warranty is given and no liability is assumed by Microchip Technology Incorporated with respect to the accuracy or use of such information, or infringement of patents or other intellectual property rights arising from such use or otherwise. Use of Microchip’s products as critical components in life support systems is not authorized except with express written approval by Microchip. No licenses are conveyed, implicitly or otherwise, under any intellectual property rights.

Note the following details of the code protection feature on Microchip devices:

- Microchip products meet the specification contained in their particular Microchip Data Sheet.
- Microchip believes that its family of products is one of the most secure families of its kind on the market today, when used in the intended manner and under normal conditions.
- There are dishonest and possibly illegal methods used to breach the code protection feature. All of these methods, to our knowledge, require using the Microchip products in a manner outside the operating specifications contained in Microchip’s Data Sheets. Most likely, the person doing so is engaged in theft of intellectual property.
- Microchip is willing to work with the customer who is concerned about the integrity of their code.
- Neither Microchip nor any other semiconductor manufacturer can guarantee the security of their code. Code protection does not mean that we are guaranteeing the product as “unbreakable.”

Code protection is constantly evolving. We at Microchip are committed to continuously improving the code protection features of our products. Attempts to break microchip’s code protection feature may be a violation of the Digital Millennium Copyright Act. If such acts allow unauthorized access to your software or other copyrighted work, you may have a right to sue for relief under that Act.

Trademarks

The Microchip name and logo, the Microchip logo, KEELOQ, MPLAB, PIC, PICmicro, PICSTART, PRO MATE and PowerSmart are registered trademarks of Microchip Technology Incorporated in the U.S.A. and other countries.

FilterLab, microID, MXDEV, MXLAB, PICMASTER, SEEVAL and The Embedded Control Solutions Company are registered trademarks of Microchip Technology Incorporated in the U.S.A.

Accuron, dsPIC, dsPICDEM.net, ECONOMONITOR, FanSense, FlexROM, fuzzyLAB, In-Circuit Serial Programming, ICSP, ICEPIC, microPort, Migratable Memory, MPASM, MPLIB, MPLINK, MPSIM, PICC, PICkit, PICDEM, PICDEM.net, PowerCal, PowerInfo, PowerTool, rPIC, Select Mode, SmartSensor, SmartShunt, SmartTel and Total Endurance are trademarks of Microchip Technology Incorporated in the U.S.A. and other countries.

Serialized Quick Turn Programming (SQTP) is a service mark of Microchip Technology Incorporated in the U.S.A.

All other trademarks mentioned herein are property of their respective companies.
