Introduction

This application note explains the communication of I²C-Compatible Master microcontroller with Atmel AT42QT1070 as a slave device. It demonstrates configuring and controlling various parameters of this device.

The host code demonstration program provided has been developed for 8-bit Atmel® megaAVR® (Atmel ATmega2560) microcontroller but can be easily adapted for other platforms.

The demonstration program is written in C and supports both GCC (Atmel Studio) and IAR™ (IAR Embedded Workbench®) compiler. The demonstration program also supports the Atmel QTouch® devices:

- AT42QT1060
- AT42QT2120
- AT42QT2160
- QT60160
- QT60240

1. **Overview of the Atmel AT42QT1070**

AT42QT1070 is a digital burst mode charge-transfer capacitive sensor driver. The device can sense from one to seven keys, dependent on mode. It can operate in either Comms mode or Standalone mode.

In Comms mode where a host can communicate with the device through the I2C-Compatible Two-Wire Interface (TWI) and up to seven keys can be configured. This allows user to configure settings for Threshold, Adjacent Key Suppression® (AKS®), Detect Integrator, Low Power (LP) mode, Guard Channel and Max On Duration for keys.

In Standalone mode, the start-up values are fixed in firmware and cannot be changed. This mode supports up to 4 keys plus a Guard Channel can be configured. The key detection is reported through their respective IOs.

The more details about the AT42QT1070 and its setup parameters can be referred in the AT42QT1070 datasheet.

2. **Circuit Configuration with Host Microcontroller**

Connection to the Host microcontroller uses the two I2C-compatible pins (SCL and SDA), CHANGE pin and the RESET pin.

Figure 2-1. Circuit configuration with Host microcontroller.

Touch keys (K0 – K6) are connected to the KEY0 to KEY6 drive signals as described in the datasheet. The demonstration program uses LEDs on host microcontroller pins PB0 to PB6 to indicate touches on keys K0 to K6.

**Notes:**

1. Pull-up resistors are required on the I2C-compatible signals (SCL and SDA). Either discrete pull-up resistors or the host microcontroller’s weak pull-ups can be used. Ensure that the pull-up resistors are connected to the same Vdd level as the AT42QT1070.

2. The CHANGE pin is open-drain and requires a 47kΩ pull-up resistor.

3. The Mode pin should be connected to Ground (Vss) to select Comms mode.
2.1 Interface timing

Figure 2-2. Atmel AT42QT1070 interface timing.

The AT42QT1070 signals any change in its sense status by driving the CHANGE pin low. Sense status includes bytes 2 and 3 of the address map. In response to the AT42QT1070 driving CHANGE low, the host reads status bytes 2 and 3. The AT42QT1070 releases the CHANGE pin when all changed status bytes have been read. Handshaking logic within the AT42QT1070 guarantees that any unread changes in any status byte will cause CHANGE to be driven low, even if this occurs while the device is being read.
3. Demonstration Program

The demonstration program shows how to use the host interface to read real time touch information from QT™ devices. It also demonstrates the procedure to read and write the setup block which helps to tune the operating parameters of the device.

3.1 Program flow

![Flowchart diagram]

- **START**
- Initialize Communication Interface
  - `InitQtInterface();`
- Reset AT42QT1070
  - `ResetQt();`
- Ensure proper communication and QT device ready state
  - `GetCommsReady();`
- Read Setup Block
  - `ReadSetupBlock();`
- Modify Parameters in Setup Block if desired
- Write Setup Block
  - `WriteSetupBlock();`
- Is CHANGE Pin asserted?
  - No
  - Read touch status on all keys
    - `ReadKeyStatus();`
  - Yes
    - Add application code
3.2 Files

The folder structure for the demonstration program is shown below.

![Folder Structure Diagram]

The source code consists of the following files:

<table>
<thead>
<tr>
<th>File name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>main.c</td>
<td>It consists the main() function and the body of the application program</td>
</tr>
<tr>
<td>configuration.h</td>
<td>Device selection and port pin selections for <code>RESET</code> and <code>CHANGE</code> pins are configured here</td>
</tr>
<tr>
<td>QT_I2C.c</td>
<td>It consists the application interfaces to drive the QT device</td>
</tr>
<tr>
<td>QT1060.h</td>
<td>Header file for the Atmel AT42QT1060 device and it consists AT42QT1060 Setup Block structure and address map enums</td>
</tr>
<tr>
<td>QT1070.h</td>
<td>Header file for the Atmel AT42QT1070 device and it consists AT42QT1070 Setup Block structure and address map enums</td>
</tr>
<tr>
<td>QT2120.h</td>
<td>Header file for the Atmel AT42QT2120 device and it consists AT42QT2120 Setup Block structure and address map enums</td>
</tr>
<tr>
<td>QT2160.h</td>
<td>Header file for the Atmel AT42QT2160 device and it consists AT42QT2160 Setup Block structure and address map enums</td>

<tr>
<td>Output</td>
<td>none</td>
</tr>
<tr>
<td>Return</td>
<td>none</td>
</tr>
<tr>
<td>*<em>uint8_t ReadSetupBlock(uint8_t ReadLength, uint8_t <em>ReadPtr)</em></em></td>
<td>Read entire setup block from QT device.</td>
</tr>
<tr>
<td>Input</td>
<td>ReadLength: Number of bytes to read</td>
</tr>
<tr>
<td>Output</td>
<td>ReadPtr: Pointer to byte array containing read-data</td>
</tr>
<tr>
<td>Return</td>
<td>TRUE if read successful, else FALSE</td>
</tr>
<tr>
<td>*<em>uint8_t WriteSetupBlock(uint8_t WriteLength, uint8_t <em>WritePtr)</em></em></td>
<td>Write entire setup block to QT-device.</td>
</tr>
<tr>
<td>Input</td>
<td>WriteLength: Number of bytes to write</td>
</tr>
<tr>
<td>Output</td>
<td>WritePtr: Pointer to byte array containing write-data</td>
</tr>
<tr>
<td>Return</td>
<td>none</td>
</tr>
<tr>
<td>*<em>uint8_t ReadKeyStatus(uint8_t ReadLength, uint8_t <em>ReadPtr)</em></em></td>
<td>Read detection status of all keys from the QT device</td>
</tr>
<tr>
<td>Input</td>
<td>ReadLength: Number of bytes to read</td>
</tr>
<tr>
<td>Output</td>
<td>ReadPtr: Pointer to byte array for read-data</td>
</tr>
<tr>
<td>Return</td>
<td>TRUE if transfer completes, else FALSE</td>
</tr>
<tr>
<td><strong>void GetCommsReady(void)</strong></td>
<td>Attempt to read the Device ID until it is read successfully. Then validate the chip ID is correct. If the chip ID is wrong, the program goes no further.</td>
</tr>
<tr>
<td>Input</td>
<td>none</td>
</tr>
<tr>
<td>Output</td>
<td>none</td>
</tr>
<tr>
<td>Return</td>
<td>TRUE if transfer completes, else FALSE</td>
</tr>
<tr>
<td><strong>void InitTouchStatusPorts(void)</strong></td>
<td>Configure the PORTB pins for displaying touch status</td>
</tr>
<tr>
<td>Input</td>
<td>none</td>
</tr>
<tr>
<td>Output</td>

<td>none</td>
</tr>
<tr>
<td>*<em>void UpdateLedStatus(uint8_t <em>QtStatusPtr)</em></em></td>
<td>Update touch key status through LED indications</td>
</tr>
<tr>
<td>Input</td>
<td>QtStatusPtr: Pointer to byte array for QTouch data</td>
</tr>
<tr>
<td>Output</td>
<td>none</td>
</tr>
<tr>
<td>Return</td>
<td>none</td>
</tr>
</tbody>
</table>

### 3.4 TWI Master driver

The demonstration program in this application note includes an interrupt-based TWI Master driver using a hardware TWI module and two port pins of the host microcontroller. The TWI communication sequences used to read and write data to the Atmel AT42QT1070 are fully described in the AT42QT1070 datasheet.

The TWI Master Driver implementation is done in the file TWI_Master.c and its header file TWI_Master.h.
### Table 3-2. TWI Master driver functions.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
</table>
| `void twi_master_initialise(uint8_t bit_rate, uint8_t pre_scalar_value)` | Initializes the TWI peripheral as Master with 100kHz speed.  
- **Input**: bit_rate: division factor for the bit rate generator (0 - 255)  
  pre_scalar_value: pre-scalar for the Bit Rate Generator  
- **Output**: none  
- **Return**: none |
| `uint8_t twi_transceiver_busy(void)` | This function to test if the TWI_ISR is busy in write/read.  
- **Input**: none  
- **Output**: none  
- **Return**: TRUE if busy, else FALSE |
| `uint8_t twi_get_state_info(void)` | This function to fetch the state information of the previous operation. The function will hold execution (loop) until the TWI_ISR has completed with the previous operation. If there was an error, then the function will return the TWI State code.  
- **Input**: none  
- **Output**: none  
- **Return**: Error state |
| `uint8_t twi_write(uint8_t slave_address, uint8_t write_address, uint8_t write_length, uint8_t *write_ptr)` | Executes multi-byte write to QT-device. The function will hold execution (loop) until the TWI_ISR has completed with the previous operation, then initialize the next operation, wait till write operation completion and return.  
- **Input**: SlaveAddress: Device address on the TWI bus  
  WriteAddress: Register address  
  WriteLength: Number of bytes to write  
  WritePtr: Pointer to byte array containing write-data  
- **Output**: none  
- **Return**: TRUE if transfer completes, else FALSE |
| `uint8_t twi_rewrite(void)` | This function to resend the last message. The driver will reuse the data previously put in the transceiver buffers. The function will hold execution (loop) until the TWI_ISR has completed with the previous operation, then initialize the next operation, wait till write operation completion and return.  
- **Input**: none  
- **Output**: none  
- **Return**: TRUE if transfer completes, else FALSE |
| `uint8_t twi_read(uint8_t slave_address, uint8_t read_address, uint8_t read_length, uint8_t *read_ptr)` | Executes multi-byte read from QT-device. The function will hold execution (loop) until the TWI_ISR has completed with the previous operation, before reading out the data and returning. If there was an error in the previous operation the function will return the TWI error code.  
- **Input**: SlaveAddress: Device address on the TWI bus  
  ReadAddress: Register address  
  ReadLength: Number of bytes to read  
- **Output**: ReadPtr: Pointer to byte array containing read-data  
- **Return**: TRUE if transfer completes, else FALSE |
| TWI_ISR | This function is the Interrupt Service Routine (ISR), and called when the TWI interrupt is triggered; that is whenever a TWI event has occurred.  
- **Input**: none  
- **Output**: none  
- **Return**: none |
4. **Porting Code to another Platforms**

This section discusses the parts of the demonstration program which needs modification while porting to other MCUs or another I²C compatible Atmel QTouch device which are listed in the introduction section.

- Do the QTouch device selection in the configuration.h file
- Define the IO port pins which are going to be used for CHANGE and RESET pin in the configuration.h file as below:

```c
// RESET port and pin configuration
#define RESET_PORT D  // PORT
#define RESET_PIN 4    // Pin Number

// CHANGE Status port and pin configuration
#define CHANGE_STATUS_PORT D // PORT
#define CHANGE_STATUS_PIN 3   // Pin Number
```

- Modify the bit_rate and pre_scalar_value arguments in the function call TWI_Master_Initialise() to change the TWI clock frequency other than 100kHz

Note: The TWI driver and IO pin configuration part of this demonstration program is ONLY compatible for all ATmega devices and some of ATtiny devices.
