Synchronous Buck Features:

- Input Voltage: 4.5V to 40V
- Output Voltage: 0.5V to 3.6V
  - Greater than 3.6V requires external divider
- Switching Frequency: 100 kHz to 1.6 MHz
- Quiescent Current: 5 mA Typical
- High-Drive:
  - +5V Gate Drive
  - 1A/2A Source Current
  - 1A/2A Sink Current
- Low-Drive:
  - +5V Gate Drive
  - 2A Source Current
  - 4A Sink Current
- Peak Current Mode Control
- Differential Remote Output Sense
- QEC-100 Qualified
- Multiple Output Systems:
  - Master or Slave
  - Frequency Synchronized
- Configurable Parameters:
  - Overcurrent Limit
  - Input Undervoltage Lockout
  - Output Overvoltage
  - Output Undervoltage
  - Internal Analog Compensation
  - Soft Start Profile
  - Synchronous Driver Dead Time
  - Switching Frequency
- Thermal Shutdown

Microcontroller Features:

- Precision 8 MHz Internal Oscillator Block:
  - Factory Calibrated
- Interrupt Capable
  - Firmware
  - Interrupt-on-Change Pins
- Only 35 Instructions to Learn
- 4096 Words On-Chip Program Memory
- High-Endurance Flash:
  - 100,000 Write Flash Endurance
  - Flash Retention: >40 years
- Watchdog Timer (WDT) with Independent Oscillator for Reliable Operation
- Programmable Code Protection
- In-Circuit Debug (ICD) via Two Pins (MCP19119)
- In-Circuit Serial Programming™ (ICSP™) via Two Pins
- 11 I/O Pins and One Input-Only Pin (MCP19118)
  - Three Open-Drain Pins
- 14 I/O Pins and One Input-Only Pin (MCP19119)
  - Three Open-Drain Pins
- Analog-to-Digital Converter (ADC):
  - 10-Bit Resolution
  - 12 Internal Channels
  - Eight External Channels
- Timer0: 8-Bit Timer/Counter with 8-Bit Prescaler
- Enhanced Timer1:
  - 16-Bit Timer/Counter with Prescaler
  - Two Selectable Clock Sources
- Timer2: 8-Bit Timer/Counter with Prescaler
  - 8-Bit Period Register
- \(^2\text{C™}\) Communication:
  - 7-Bit Address Masking
  - Two Dedicated Address Registers
  - SMBus/PMBus™ Compatibility

**Note**

1: The Analog Debug Output is selected when the ATSTCON<BNCHEN> bit is set.

2: Selected when the device is functioning as multiple output master or slave by proper configuration of the MLTPH<2:0> bits in the BUFFCON register.

3: Selected when the device is functioning as multi-phase master or slave by proper configuration of the MLTPH<2:0> bits in the BUFFCON register.

4: The IOC is disabled when MCLR is enabled.

5: Weak pull-up always enabled when MCLR is enabled, otherwise the pull-up is under user control.

TO OUR VALUED CUSTOMERS

It is our intention to provide our valued customers with the best documentation possible to ensure successful use of your Microchip products. To this end, we will continue to improve our publications to better suit your needs. Our publications will be refined and enhanced as new volumes and updates are introduced.

If you have any questions or comments regarding this publication, please contact the Marketing Communications Department via E-mail at docerrors@microchip.com. We welcome your feedback.

Most Current Data Sheet

To obtain the most up-to-date version of this data sheet, please register at our Worldwide Web site at:

   http://www.microchip.com

You can determine the version of a data sheet by examining its literature number found on the bottom outside corner of any page. The last character of the literature number is the version number, (e.g., DS30000000A is version A of document DS30000000).

Errata

An errata sheet, describing minor operational differences from the data sheet and recommended workarounds, may exist for current devices. As device/documentation issues become known to us, we will publish an errata sheet. The errata will specify the revision of silicon and revision of document to which it applies.

To determine if an errata sheet exists for a particular device, please check with one of the following:

• Microchip’s Worldwide Web site; http://www.microchip.com
• Your local Microchip sales office (see last page)

When contacting a sales office, please specify which device, revision of silicon and data sheet (include literature number) you are using.

Customer Notification System

Register on our web site at www.microchip.com to receive the most current information on all of our products.
1.0 DEVICE OVERVIEW

The MCP19118/19 is a highly integrated, mixed signal, analog pulse-width modulation (PWM) current mode controller with an integrated microcontroller core for synchronous DC/DC step-down applications. Since the MCP19118/19 uses traditional analog control circuitry to regulate the output of the DC/DC converter, the integration of the PIC® microcontroller mid-range core is used to provide complete customization of device operating parameters, start-up and shutdown profiles, protection levels and fault handling procedures.

The MCP19118/19 is designed to efficiently operate from a single 4.5V to 40V supply. It features integrated synchronous drivers, bootstrap device, internal linear regulator and 4 kV nonvolatile memory, all in a space-saving 24-pin 4 mm x 4 mm QFN package (MCP19118) or 28-pin 5 mm x 5 mm QFN package (MCP19119).

After initial device configuration using Microchip's MPLAB® X Integrated Development Environment (IDE) software, the PMBus or I²C can be used by a host to communicate with, or modify, the operation of the MCP19118/19.

Two internal linear regulators generate two 5V rails. One 5V rail is used to provide power for the internal analog circuitry and is contained on-chip. The second 5V rail provides power to the PIC device and is present on the VDD pin. It is recommended that a 1 µF capacitor be placed between VDD and PGND. The VDD pin may also be directly connected to the VDR pin or connected through a low-pass RC filter. The VDR pin provides power to the internal synchronous driver.

FIGURE 1-1: TYPICAL APPLICATION CIRCUIT

[Diagram of the typical application circuit showing the connections and labels for VIN, VOUT, GPIO, SDA, SCL, VDD, VDRV, PHASE, HDRV, BOOT, MOSFETs, capacitors, and other components relevant to the device description.]

2.0 PIN DESCRIPTION

The MCP19118/19 family of devices features pins that have multiple functions associated with each pin. Table 2-1 provides a description of the different functions. See Section 2.1 “Detailed Pin Functional Description” for more detailed information.

3: Selected when the device is functioning as multi-phase master or slave by proper configuration of the MLTPH<2:0> bits in the BUFFCON register.
2.1 Detailed Pin Functional Description

2.1.1 GPA0 PIN
GPA0 is a general purpose TTL input or CMOS output pin whose data direction is controlled in TRISGPA. An internal weak pull-up and interrupt-on-change are also available.

AN0 is an input to the A/D. To configure this pin to be read by the A/D on channel 0, bits TRISA0 and ANSA0 must be set.

When the ATSTCON<BNCHEN> bit is set, this pin is configured as the ANALOG_TEST function. It is a buffered output of the internal analog signal multiplexer. Signals present on this pin are controlled by the BUFFCON register.

2.1.2 GPA1 PIN
GPA1 is a general purpose TTL input or CMOS output pin whose data direction is controlled in TRISGPA. An internal weak pull-up and interrupt-on-change are also available.

AN1 is an input to the A/D. To configure this pin to be read by the A/D on channel 1, bits TRISA1 and ANSA1 must be set.

When the MCP19118/19 is configured as a multiple output or multi-phase master or slave, this pin is configured to be the switching frequency synchronization input or output, CLKPIN. See Section 3.10.6 “Multi-Phase System” and Section 3.10.7 “Multiple Output System” for more information.

2.1.3 GPA2 PIN
GPA2 is a general purpose TTL input or CMOS output pin whose data direction is controlled in TRISGPA. An internal weak pull-up and interrupt-on-change are also available.

AN2 is an input to the A/D. To configure this pin to be read by the A/D on channel 2, bits TRISA2 and ANSA2 must be set.

When bit T0CS is set, the T0CKI function is enabled. See Section 23.0 “Timer0 Module” for more information.

GPA2 can also be configured as an external interrupt by setting the INTE bit. See Section 15.2 “GPA2/INT Interrupt” for more information.

2.1.4 GPA3 PIN
GPA3 is a general purpose TTL input or CMOS output pin whose data direction is controlled in TRISGPA. An internal weak pull-up and interrupt-on-change are also available.

AN3 is an input to the A/D. To configure this pin to be read by the A/D on channel 3, bits TRISA3 and ANSA3 must be set.

2.1.5 GPA4 PIN
GPA4 is a true open-drain general purpose pin whose data direction is controlled in TRISGPA. There is no internal connection between this pin and the device VDD, making this pin ideal to be used as an SMBus Alert pin. This pin does not have a weak pull-up, but interrupt-on-change is available.

2.1.6 GPA5 PIN
GPA5 is a general purpose TTL input-only pin. An internal weak pull-up and interrupt-on-change are also available.

For programming purposes, this pin is to be connected to the MCLR pin of the serial programmer. See Section 28.0 “In-Circuit Serial Programming™ (ICSP™)” for more information.

2.1.7 GPA6 PIN
GPA6 is a general purpose CMOS input/output pin whose data direction is controlled in TRISGPA. An interrupt-on-change is also available.

On the MCP19118, the ISCPDAT is the serial programming data input function. This is used in conjunction with ICSPCLK to serial program the device. This pin function is only implemented on the MCP19118.

2.1.8 GPA7 PIN
GPA7 is a true open-drain general purpose pin whose data direction is controlled in TRISGPA. There is no internal connection between this pin and the device VDD. This pin does not have a weak pull-up, but interrupt-on-change is available.

When the MCP19118/19 is configured for I2C communication (see Section 27.2 “I2C Mode Overview”), GPA7 functions as the I2C clock, SCL.

On the MCP19118, the ISCPCLK is the serial programming clock function. This is used in conjunction with ISCPDAT to serial program the device. This pin function is only implemented on the MCP19118.

2.1.9 GPB0 PIN
GPB0 is a true open-drain general purpose pin whose data direction is controlled in TRISGPB. There is no internal connection between this pin and the device VDD. This pin does not have a weak pull-up, but interrupt-on-change is available.

When the MCP19118/19 is configured for I2C communication (see Section 27.2 “I2C Mode Overview”), GPB0 functions as the I2C clock, SDA.
2.1.10 GPB1 PIN

GPB1 is a general purpose TTL input or CMOS output pin whose data direction is controlled in TRISGPB. An internal weak pull-up and interrupt-on-change are also available.

AN4 is an input to the A/D. To configure this pin to be read by the A/D on channel 4, bits TRISB1 and ANSB1 must be set.

When the MCP19118/19 is configured as a multiple output or multi-phase master or slave, this pin is configured to be the error amplifier signal input or output. See Section 3.10.6 “Multi-Phase System” and Section 3.10.7 “Multiple Output System” for more information.

2.1.11 GPB2 PIN

GPB2 is a general purpose TTL input or CMOS output pin whose data direction is controlled in TRISGPB. An internal weak pull-up and interrupt-on-change are also available.

AN5 is an input to the A/D. To configure this pin to be read by the A/D on channel 5, bits TRISB2 and ANSB2 must be set.

2.1.12 GPB4 PIN

This pin and its associated functions are only available on the MCP19119 device.

GPB4 is a general purpose TTL input or CMOS output pin whose data direction is controlled in TRISGPB. An internal weak pull-up and interrupt-on-change are also available.

AN6 is an input to the A/D. To configure this pin to be read by the A/D on channel 6, bits TRISB4 and ANSB4 must be set.

On the MCP19119, the ISCPDAT is the serial programming data input function. This is used in conjunction with ICSPCLK to serial program the device. This pin function is only implemented on the MCP19119.

2.1.13 GPB5 PIN

This pin and its associated functions are only available on the MCP19119 device.

GPB5 is a general purpose TTL input or CMOS output pin whose data direction is controlled in TRISGPB. An internal weak pull-up and interrupt-on-change are also available.

AN7 is an input to the A/D. To configure this pin to be read by the A/D on channel 7, bits TRISB5 and ANSB5 must be set.

On the MCP19119, the ISCPCLK is the serial programming clock function. This is used in conjunction with ISCPDAT to serial program the device. This pin function is only implemented on the MCP19119.

This pin can also be configured as an alternate switching frequency synchronization input or output, ALT_CLKPIN, for use in multiple output or multi-phase systems. See Section 19.1 “Alternate Pin Function” for more information.

2.1.14 GPB6 PIN

This pin and its associated functions are only available on the MCP19119 device.

GPB6 is a general purpose TTL input or CMOS output pin whose data direction is controlled in TRISGPB. An internal weak pull-up and interrupt-on-change are also available.

2.1.15 GPB7 PIN

This pin and its associated functions are only available on the MCP19119 device.

GPB7 is a general purpose TTL input or CMOS output pin whose data direction is controlled in TRISGPB. An internal weak pull-up and interrupt-on-change are also available.

2.1.16 VIN PIN

Device input power connection pin. It is recommended that capacitance be placed between this pin and the GND pin of the device.

2.1.17 VDD PIN

The output of the internal +5.0V regulator is connected to this pin. It is recommended that a 1.0 µF bypass capacitor be connected between this pin and the GND pin of the device. The bypass capacitor should be placed physically close to the device.

2.1.18 VDR PIN

The 5V supply for the low-side driver is connected to this pin. The pin can be connected by an RC filter to the VDD pin.

2.1.19 GND PIN

GND is the small signal ground connection pin. This pin should be connected to the exposed pad on the bottom of the package.

2.1.20 PGND PIN

Connect all large signal level ground returns to PGND. These large-signal level ground traces should have a small loop area and minimal length to prevent coupling of switching noise to sensitive traces.

2.1.21 LDRV PIN

The gate of the low-side or rectifying MOSFET is connected to LDRV. The PCB trace connecting LDRV to the gate must be of minimal length and appropriate width to handle the high peak drive currents and fast voltage transitions.
2.1.22 HDRV PIN
The gate of the high-side MOSFET is connected to HDRV. This is a floating driver referenced to PHASE. The PCB trace connecting HDRV to the gate must be of minimal length and appropriate width to handle the high-peak drive current and fast voltage transitions.

2.1.23 PHASE PIN
The PHASE pin provides the return path for the high-side gate driver. The source of the high-side MOSFET, the drain of the low-side MOSFET and the inductor are connected to this pin.

2.1.24 BOOT PIN
The BOOT pin is the floating bootstrap supply pin for the high-side gate driver. A capacitor is connected between this pin and the PHASE pin to provide the necessary charge to turn on the high-side MOSFET.

2.1.25 +VSEN PIN
The noninverting input of the unity gain amplifier used for output voltage remote sensing is connected to the +VSEN pin. This pin can be internally pulled-up to VDD by setting the PE1<PUEN> bit.

2.1.26 -VSEN PIN
The inverting input of the unity gain amplifier used for output voltage remote sensing is connected to the -VSEN pin. This pin can be internally pulled-down to GND by setting the PE1<PDEN> bit.

2.1.27 +ISEN PIN
The noninverting input of the current sense amplifier is connected to the +ISEN pin.

2.1.28 -ISEN PIN
The inverting input of the current sense amplifier is connected to the -ISEN pin.

2.1.29 EXPOSED PAD (EP)
There is no internal connection to the Exposed Thermal Pad. The EP should be connected to the GND pin and to the GND PCB plane to aid in the removal of the heat.
3.0 FUNCTIONAL DESCRIPTION

3.1 Linear Regulators

Two internal linear regulators generate two 5V rails. One 5V rail is used to provide power for the internal analog circuitry and is contained on-chip. The second 5V rail provides power to the internal PIC core and is present on the VDD pin. It is recommended that a 1 µF capacitor be placed between VDD and PGGND.

The VDR pin provides power to the internal synchronous MOSFET driver. VDD can be directly connected to VDR or connected through a low-pass RC filter to provide noise filtering. A 1 µF ceramic bypass capacitor should be placed between VDR and PGGND. When connecting VDD to VDR, the gate drive current required to drive the external MOSFETs must be added to the MCP19118/19 quiescent current, IQ(max). This total current must be less than the maximum current, IDD-OUT, available from VDD, that is specified in Section 4.2 “Electrical Characteristics”.

EQUATION 3-1: TOTAL REGULATOR CURRENT

\[ I_{DD-OUT} > (I_Q + I_{DRIVE} + I_{EXT}) \]

Where:
- \( I_{DD-OUT} \) is the total current available from VDD
- \( I_Q \) is the device quiescent current
- \( I_{DRIVE} \) is the current required to drive the external MOSFETs
- \( I_{EXT} \) is the amount of current used to power additional external circuitry

EQUATION 3-2: GATE DRIVE CURRENT

\[ I_{DRIVE} = (Q_{gHIGH} + Q_{gLOW}) \times F_{SW} \]

Where:
- \( I_{DRIVE} \) is the current required to drive the external MOSFETs
- \( Q_{gHIGH} \) is the total gate charge of the high-side MOSFET
- \( Q_{gLOW} \) is the total gate charge of the low-side MOSFET
- \( F_{SW} \) is the switching frequency

Alternatively, an external regulator can be used to power the synchronous driver. An external 5V source can be connected to VDR. The amount of current required from this external source can be found in Equation 3-2. Care must be taken that the voltage applied to VDR does not exceed the maximum ratings found in Section 4.1 “Absolute Maximum Ratings(†)”.

3.2 Internal Synchronous Driver

The internal synchronous driver is capable of driving two N-Channel MOSFETs in a synchronous rectified buck converter topology. The gate of the floating MOSFET is connected to the HDRV pin. The source of this MOSFET is connected to the PHASE pin. The HDRV pin source and sink current is configurable. By setting the PE1<DRVWSTR> bit, the high-side is capable of sourcing and sinking a peak current of 1A. By clearing this bit, the source and sink peak current is 2A.

Note 1: The PE1<DRVWSTR> bit configures the peak source/sink current of the HDRV pin.

The MOSFET connected to the LDRV pin is not floating. The low-side MOSFET gate is connected to the LDRV pin and the source of this MOSFET is connected to PGGND. The drive strength of the LDRV pin is not configurable. This pin is capable of sourcing a peak current of 2A. The peak sink current is 4A. This helps keep the low-side MOSFET off when the high-side MOSFET is turning on.

Note 1: Refer to Figure 1-1 for a graphical representation of the MOSFET connections.

3.2.1 MOSFET DRIVER DEAD TIME

The MOSFET driver dead time is defined as the time between one drive signal going low and the complimentary drive signal going high. Refer to Figure 6-2. The MCP19118/19 has the capability to adjust both the high-side and low-side driver dead time independently. The adjustment of the driver dead time is controlled by the DEADCON register and is adjustable in 4 ns increments.

Note 1: The DEADCON register controls the amount of dead time added to the HDRV or LDRV signal. The dead time circuitry is enabled by the PE1<LDLYBY> and PE1<HDLYBY> bits.

3.2.2 MOSFET DRIVER CONTROL

The MCP19118/19 has the ability to disable the entire synchronous driver or just one side of the synchronous drive signal. The bits that control the MOSFET driver can be found in Register 8-1.

By setting the ATSTCON<DRVDIS> bit, the entire synchronous driver is disabled. The HDRV and LDRV signals are set low and the PHASE pin is floating. Clearing this bit allows normal operation.

Individual control of the HDRV or LDRV signal is accomplished by setting or clearing the ATSTCON<HIDIS> or ATSTCON<LODIS> bits. When either driver is disabled, the output signal is set low.
3.3 Output Voltage

The output voltage is configured by the settings contained in the OVCCON and OVFCON registers. No external resistor divider is needed to set the output voltage. Refer to Section 6.10 “Output Voltage Configuration”.

The MCP19118/19 contains a unity gain differential amplifier used for remote sensing of the output voltage. Connect the +VSEN and -VSEN pins directly at the load for better load regulation. The +VSEN and -VSEN are the positive and negative inputs, respectively, of the differential amplifier.

3.4 Switching Frequency

The switching frequency is configurable over the range of 100 kHz to 1.6 MHz. The Timer2 module is used to generate the HDRV/LDRV switching frequency. Refer to Section 26.0 “PWM Module” for more information. Example 3-1 shows how to configure the MCP19118/19 for a switching frequency of 300 kHz.

EXAMPLE 3-1: CONFIGURING FSW

| BANKSEL T2CON | CLRF T2CON ;Turn off Timer2 | CLRF TMR2 ;Initialize module | MOVLW 0x19 ;Fsw=300 kHz | MOVWF PR2 |
| MOVLW 0x0A ;Max duty cycle=40% | MOVWF PWMRL | MOVLW 0x00 ;No phase shift | MOVWF PWMPHL | MOVLW 0x04 ;Turn on Timer2 | MOVWF T2CON |

3.5 Compensation

The MCP19118/19 is an analog peak current mode controller with integrated adjustable compensation. The CMPZCON register is used to adjust the compensation zero frequency and gain. Figure 3-1 shows the internal compensation network with the output differential amplifier.

FIGURE 3-1: SIMPLIFIED INTERNAL COMPENSATION

3.6 Slope Compensation

In current mode control systems, slope compensation needs to be added to the control path to help prevent subharmonic oscillation when operating with greater than 50% duty cycle. In the MCP19118/19, a negative slope is added to the error amplifier output signal before it is compared to the current sense signal. The amount of slope added is controlled by the SLPCRCON register.

Note 1: To enable the slope compensation circuitry, the ABECON<SLCPBY> bit must be cleared.

The amount of slope compensation added should be equal to the inductor current down slope during the high-side off time.

3.7 Current Sense

The output current is differentially sensed by the MCP19118/19. The sense element can be either a resistor placed in series with the output or the series resistance of the inductor. If the inductor series resistance is used, a filter is needed to remove the large AC component of the voltage that appears across the inductor and leave only the small AC voltage that appears across the inductor resistance, as shown in Figure 3-2. This small AC voltage is representative of the output current.

FIGURE 3-2: INDUCTOR CURRENT SENSE FILTER

The value of RS and CS can be found by using Equation 3-3. When the current sense filter time constant is set equal to the inductor time constant, the voltage appearing across CS approximates the current flowing in the inductor, multiplied by the inductor resistance.
EQUATION 3-3: CALCULATING FILTER VALUES

\[
\frac{L}{R_L} = (R_S \times C_S)
\]

Where:
- \( L \) is the inductance value of the output inductor
- \( R_L \) is the series resistance of the output inductor
- \( R_S \) is the current sense filter resistor
- \( C_S \) is the current sense filter capacitor

Both AC gain and DC gain can be added to the current sense signal. Refer to Section 6.3 “Current Sense AC Gain” and Section 6.4 “Current Sense DC Gain” for more information.

3.7.1 PLACEMENT OF THE CURRENT SENSE FILTER COMPONENTS

The amplitude of the current sense signal is typically less than 100 mV peak-to-peak. Therefore, the small signal current sense traces are very susceptible to circuit noise. When designing the printed circuit board, placement of \( R_S \) and \( C_S \) is very important. The \(+I_{SEN}\) and \(-I_{SEN}\) traces should be routed parallel to each other with minimum spacing. This Kelvin sense routing technique helps minimize noise sensitivity. The filter capacitor, \( C_S \), should be placed as close to the MCP19118/19 as possible. This will help filter any noise that is injected onto the current sense lines. The trace connecting \( C_S \) to the inductor should occur directly at the inductor and not at any other \(+V_{SEN}\) trace. The filter resistor, \( R_S \), should be placed close to the inductor. See Figure 3-3 for component placement. Care should also be taken to avoid routing the \(+I_{SEN}\) and \(-I_{SEN}\) traces near the high current switching nodes of the HDRV, LDRV, PHASE or BOOST traces. It is recommended that a ground layer be placed between these high current traces and the small signal current sense traces.

FIGURE 3-3: CURRENT SENSE FILTER COMPONENT PLACEMENT

3.8 Protection Features

3.8.1 INPUT UNDERVOLTAGE LOCKOUT
The input undervoltage lockout (UVLO) threshold is configurable by the VINLVL register. When the voltage at the VIN pin of the MCP19118/19 is below the configurable threshold, the PIR2<VINIF> flag will be set. This flag is cleared by hardware once the VIN voltage is greater than the configurable threshold. By enabling the global interrupts or polling the VINIF bit, the MCP19118/19 can be disabled when the VIN voltage is below the threshold.

Note 1: The UVLO DAC must be enabled by setting the VINLVL<UVLOEN> bit.

2: Interrupt flag bits are set when an interrupt condition occurs, regardless of the state of its corresponding enable bit or the Global Interrupt Enable (GIE) bit in the INTCON register.

Some techniques that can be used to disable the switching of the MCP19118/19 while the VINIF flag is set include setting the ATSTCON<DVRDIS> bit, setting the reference voltage to 0V, setting the PE1<PUEN> bit or setting the ATSTCON<HIDIS> and ATSTCON<LODIS> bits.

3.8.2 OUTPUT OVERCURRENT
The MCP19118/19 senses the voltage drop across the high-side MOSFET to determine when an output overcurrent (OC) exists. This voltage drop is configurable by the OCCON register and is measured when the high-side MOSFET is conducting. To avoid false OC events, leading edge blanking is applied to the measurements. The amount of blanking is controlled by the OCLEB<1:0> bits in the OCCON register. See Section 6.2 “Output Overcurrent” for more information.

Note 1: The OC DAC must be enabled by setting the OCCON<OCEN> bit.

3.8.3 OUTPUT UNDERVOLTAGE
When the output undervoltage DAC is enabled by setting the ABECON<UVDCEN> bit, the voltage measured between the +VSEN and −VSEN pins is monitored and compared to the UV threshold controlled by the OUVCON register. When the output voltage is below the threshold, the PIR2<UVIF> flag will be set. Once set, firmware can determine how the MCP19118/19 responds to the fault condition and it must clear the UVIF flag.

By setting the PE1<UVTEE> bit, the HDRV and LDRV signals will be asserted low when the UVIF flag is set. The signals will remain low until the flag is cleared.

Note 1: The UV DAC must be enabled by setting the ABECON<UVDCEN> bit.

2: Interrupt flag bits are set when an interrupt condition occurs, regardless of the state of its corresponding enable bit or the Global Interrupt Enable (GIE) bit in the INTCON register.

3: The output of the remote sense comparator is compared to the UV threshold. Therefore, the offset in this comparator should be considered when calculating the UV threshold.

3.8.4 OUTPUT OVERVOLTAGE
When the output overvoltage DAC is enabled by setting the ABECON<OVDCEN> bit, the voltage measured between the +VSEN and −VSEN pins is monitored and compared to the OV threshold controlled by the OOVCON register. When the output voltage is above the threshold, the PIR2<OVIF> flag will be set. Once set, firmware can determine how the MCP19118/19 responds to the fault condition and it must clear the OVIF flag.

By setting the PE1<OVTEE> bit, the HDRV and LDRV signals will be asserted low when the OVIF flag is set. The signals will remain low until the flag is cleared.

Note 1: The OV DAC must be enabled by setting the ABECON<OVDCEN> bit.

2: Interrupt flag bits are set when an interrupt condition occurs, regardless of the state of its corresponding enable bit or the Global Interrupt Enable (GIE) bit in the INTCON register.

3: The output of the remote sense comparator is compared to the OV threshold. Therefore, the offset in this comparator should be considered when calculating the OV threshold.
3.8.5 OVERTEMPERATURE

The MCP19118/19 features a hardware overtemperature shutdown protection typically set at +160°C. No firmware fault-handling procedure is required to shutdown the MCP19118/19 for an overtemperature condition.

3.9 PIC Microcontroller Core

Integrated into the MCP19118/19 is the PIC microcontroller mid-range core. This is a fully functional microcontroller, allowing proprietary features to be implemented. Setting the CONFIG<CP> bit enables the code protection. The firmware is then protected from external reads or writes. Various status and fault bits are available to customize the fault handling response.

A minimal amount of firmware is required to properly configure the MCP19118/19. Section 6.0 “ Configuring the MCP19118/19” contains detailed information about each register that needs to be set for the MCP19118/19 device to operate. To aid in the development of the required firmware, a Graphical User Interface (GUI) has been developed. This GUI can be used to quickly configure the MCP19118/19 for basic operation. Customized or proprietary features can then be added to the GUI-generated firmware.

3.10 Miscellaneous Features

3.10.1 DEVICE ADDRESSING

The communication address of the MCP19118/19 is stored in the SSPADD register. This value can be loaded when the device firmware is programmed or configured by external components. By reading a voltage on a GPIO with the ADC, a device-specific address can be stored into the SSPADD register.

The MCP19118/19 contains a second address register, SSPADD2. This is a 7-bit address that can be used as the SMBus alert address when PMBus communication is used. See Section 27.0 “Master Synchronous Serial Port (MSSP) Module” for more information.

3.10.2 DEVICE ENABLE

A GPIO pin can be configured to be a device enable pin. By configuring the pin as an input, the PORT register or the interrupt-on-change (IOC) can be used to enable the device. Example 3-2 shows how to configure a GPIO as an enable pin by testing the PORTGPA register.

EXAMPLE 3-2: CONFIGURING GPA3 AS DEVICE ENABLE

Note 1: The GUI can be found on the MCP19118/19 product page on www.microchip.com.

2: Microchip’s MPLAB X Integrated Development Environment Software is required to use the GUI.

The MCP19118/19 device features firmware debug support. See Section 30.0 “Development Support” for more information.

```
3.10.3 OUTPUT POWER GOOD

The output voltage measured between the +VSEN and -VSEN pins can be monitored by the internal ADC. In firmware, when this ADC reading matches a user-defined power good value, a GPIO can be toggled to indicate the system output voltage is within a specified range. Delays, hysteresis and time-out values can all be configured in firmware.

3.10.4 OUTPUT VOLTAGE SOFT START

During start-up, soft start of the output voltage is accomplished in firmware. By using one of the internal timers and incrementing the OVCON or OVFCON register on a timer overflow, very long soft start times can be achieved.

3.10.5 OUTPUT VOLTAGE TRACKING

The MCP19118/19 can be configured to track another voltage signal at start-up or shutdown. The ADC is configured to read a GPIO that has the desired tracking voltage applied to it. The firmware then handles the tracking of the internal output voltage reference to this ADC reading.

3.10.6 MULTI-PHASE SYSTEM

In a multi-phase system, the output of each converter is connected together. There is one master device that sets the system switching frequency and provides each slave device with an error signal, in order to regulate the output to the same value.

The MCP19118/19 can be configured as a multi-phase master or slave by setting the MLTPH<2:0> bits in the BUFFCON register. When set as a multi-phase master device, the internal switching frequency clock is connected to GPA1 and the output of the error amplifier is connected to GPB1. The GPIOs need to be configured as outputs.

When set as a multi-phase slave device, the GPA1 pin is configured as the CLKPIN function. The switching frequency clock from the master device must be connected to GPA1. The slave device will synchronize its internal switching frequency clock to the master clock. Phase shift can be applied by setting the PWMPHL register of the slave device. The slave GPB1 pin is configured as the error signal input pin (EAPIN). The master error amplifier output must be connected to GPB1. Gain can be added to the master error amplifier output signal by the SLVGNCON register setting (Register 6-8). The slave device will use this master error signal to regulate the output voltage. When set as a slave device, GPA1 and GPB1 need to be configured as inputs. Refer to Section 26.1 “Standard Pulse-Width Modulation (PWM) Mode” for additional information.

3.10.7 MULTIPLE OUTPUT SYSTEM

In a multiple output system, the switching frequency of each converter should be synchronized to a master clock to prevent beat frequencies from developing. Phase shift is often added to the master clock to help smooth the system input current. The MCP19118/19 has the ability to function as a multiple output master or slave by setting the appropriate MLTPH<2:0> bits in the BUFFCON register.

When configured as a multiple output master, the GPA1 pin is set as the CLKPIN output function. The internal switching frequency clock is applied to this pin and is to be connected to the GPA1 pin of the slave units.

When configured as a multiple output slave, the GPA1 pin is set as the CLKPIN input function. The switching frequency clock of the master device is connected to this pin. Phase shift can be applied by appropriately setting the PWMPHL register of the slave device. Refer to Section 26.1 “Standard Pulse-Width Modulation (PWM) Mode”.

3.10.8 SYSTEM BENCH TESTING

The MCP19118/19 is a highly integrated controller. To facilitate system prototyping, various internal signals can be measured by configuring the MCP19118/19 in Bench Test mode. To accomplish this, the ATSTCON<BNCHEN> bit is set. This configures GPA0 as the ANALOG_TEST feature. The signals measured on GPA0 are controlled by the ASEL<4:0> bits in the BUFFCON register. See Section 8.0 “System Bench Testing” for more information.

Note 1: The factory-set calibration words are write-protected even when the MCP19118/19 is placed in Bench Test mode.

Note 1: The ALT_CLKPIN can also be used by setting the APFCON<CLKSEL> bit. This function is only available in the MCP19119.

† Notice: Stresses above those listed under “Maximum Ratings” may cause permanent damage to the device. This is a stress rating only and functional operation of the device at those or any other conditions above those indicated in the operational listings of this specification is not implied. Exposure to maximum rating conditions for extended periods may affect device reliability.
## 4.2 Electrical Characteristics

**Electrical Specifications:** Unless otherwise noted, \( V_{IN} = 12V, V_{REF} = 1.2V, F_{SW} = 300 kHz, T_A = +25°C \). **Boldface** specifications apply over the \( T_A \) range of -40°C to +125°C.

  - GO
  - SAMPLE

- **Note 1:** If the A/D clock source is selected as RC, a time of \(T_C\) is added before the A/D clock starts. This allows the SLEEP instruction to be executed.
FIGURE 5-8: A/D CONVERSION TIMING (SLEEP MODE)

Note 1: If the A/D clock source is selected as RC, a time of $T_{CY}$ is added before the A/D clock starts. This allows the SLEEP instruction to be executed.
6.0 CONFIGURING THE MCP19118/19

The MCP19118/19 is an analog controller with digital peripheral. This means that device configuration is handled through register settings instead of adding external components. The following sections detail how to set the analog control registers.

6.1 Input Undervoltage Lockout

The VINLVL register contains the digital value that sets the input undervoltage lockout. When the input voltage on the VIN pin to the MCP19118/19 is below this programmed level, the INTCON<VINIF> flag will be set. This bit is automatically cleared when the MCP19118/19 VIN voltage rises above this programmed level.

Note: The VINIF interrupt flag bit is set when an interrupt condition occurs, regardless of the state of its corresponding enable bit or the Global Interrupt Enable (GIE) bit in the INTCON register.

REGISTER 6-1: VINLVL: INPUT UNDERVOLTAGE LOCKOUT CONTROL REGISTER

bit 5-0  
UVLO<5:0>: Undervoltage Lockout Configuration bits
UVLO<5:0> = 26.5\times\ln(UVLOSET\_POINT/4)
6.2 Output Overcurrent

The MCP19118/19 features a cycle-by-cycle peak current limit. By monitoring the OCIF interrupt flag, custom overcurrent fault handling can be implemented.

To detect an output overcurrent, the MCP19118/19 senses the voltage drop across the high-side MOSFET while it is conducting. Leading edge blanking is incorporated to mask the overcurrent measurement for a given amount of time. This helps prevent false overcurrent readings.

When an output overcurrent is sensed, the OCIF flag is set and the high-side drive signal is immediately terminated. Without any custom overcurrent handling implemented, the high-side drive signal will be asserted high at the beginning of the next clock cycle. If the overcurrent condition still exists, the high-drive signal will again be terminated.

The OCIF interrupt flag must be cleared in software. However, if a subsequent switching cycle without an overcurrent condition has not occurred, hardware will immediately set the OCIF interrupt flag.

The OCCON register contains the bits used to configure both the output overcurrent limit and the amount of leading edge blanking (see Register 6-2).

The OCCON<OCEN> bit must be set to enable the input overcurrent circuitry.

Note: The OCIF interrupt flag bit is set when an interrupt condition occurs, regardless of the state of its corresponding enable bit or the Global Interrupt Enable (GIE) bit in the INTCON register.

11111 = 625 mV drop
6.3 Current Sense AC Gain

The current measured across the inductor is a square wave that is averaged by the capacitor \(C_Q\) connected between \(+I_{SEN}\) and \(-I_{SEN}\). This very small voltage plus the ripple can be amplified by the current sense AC gain circuitry. The amount of gain is controlled by the CSGSCON register.

| 1111 | 22.0 dB |
6.4 Current Sense DC Gain

DC gain can be added to the sensed inductor current to allow it to be read by the ADC. The amount of DC gain added is controlled by the CSDGCON register.

Adding DC gain to the current sense signal used by the control loop may also be needed in some multi-phase systems to account for device and component differences. The CSDGEN bit determines if the gained current sense signal is added back to the AC current signal (see Register 6-4). If the CSDGEN bit is cleared, DC gain can still be added but the gained signal is not added back to the AC current signal.

000 = 19.5 dB
001 = 21.8 dB
010 = 24.1 dB
011 = 26.3 dB
100 = 28.6 dB
101 = 30.9 dB
110 = 33.2 dB
111 = 35.7 dB
6.5 Voltage for Zero Current

In multi-phase systems, it may be necessary to provide some offset to the sensed inductor current. The VZCCON register can be used to provide a positive or negative offset in the sensed current. Typically, the VZCCON will be set to 0x80h, which corresponds to the sensed inductor current centered around 1.45V. However, by adjusting the VZCCON register, this centered voltage can be shifted up or down by approximately 3.28 mV per step.

### 6.6 Compensation Setting

The MCP19118/19 uses a peak current mode control architecture. A control reference is used to regulate the peak current of the converter directly. The inner current loop essentially turns the inductor into a voltage-controlled current source. This reduces the control-to-output transfer function to a simple single-pole model of a current source feeding a capacitor. The desired response of the overall loop can be tuned by proper placement of the compensation zero frequency and gain. Figure 6-1 shows a simplified drawing of the internal compensation. See Register 6-6 for the adjustable zero frequency and gain settings.

6.7 Slope Compensation

A negative voltage slope is added to the output of the error amplifier. This is done to prevent subharmonic instability when:

1. the operating duty cycle is greater than 50%
2. wide changes in the duty cycle occur.

The amount of negative slope added to the error amplifier output is controlled by Register 6-7.

The slope compensation is enabled by setting the ABECON<SLCPBY> bit.

bit 3-0 SLPS<3:0>: Slope Compensation \( \Delta V/\Delta t \) Configuration bits

6.7.1 SLPS<3:0> CONFIGURATION

The SLPS<3:0> bits directly control the \( \Delta V/\Delta t \) of the added ramp. This byte should be set proportional to the switching frequency according to the following equation:

\[
\text{EQUATION 6-1:} \quad \frac{\Delta V}{\Delta t} = \frac{F_{SW} \cdot n}{1000}
\]

Where:

\( F_{SW} \) = Device switching frequency
\( n \) = Decimal equivalent of SLPS<3:0>
6.8 MASTER Error Signal Gain

When operating in a multi-phase system, the output of the MASTER’s error amplifier is used by all SLAVE devices as their control signal. It is important to balance the current in all phases to maintain a uniform temperature across all phases. Component tolerances make this balancing difficult. Each SLAVE device has the ability to gain or attenuate the MASTER error signal depending upon the settings in the SLVGNCON register.

6.10 Output Voltage Configuration

Two registers control the error amplifier reference voltage. The reference is coarsely set in 15 mV steps and then finely adjusted in 0.82 mV steps above the coarse setting (see Registers 6-10 and 6-11). Higher output voltages can be achieved by using a voltage divider connected between the output and the +VSEN pin. Care must be taken to ensure maximum voltage rating compliance on all pins.

6.13 Analog Peripheral Control
The MCP19118/19 has various analog peripherals. These peripherals can be configured to allow customizable operation. Refer to Register 6-14 for more information.

6.13.1 DIODE EMULATION MODE
The MCP19118/19 can operate in either Diode Emulation or Synchronous Rectification mode. When operating in Diode Emulation mode, the LDRV signal is terminated when the voltage across the low-side MOSFET is approximately 0V. This condition is true when the inductor current reaches approximately 0A. Both the HDRV and LDRV signals are low until the beginning of the next switching cycle. At that time, the HDRV signal is asserted high, turning on the high-side MOSFET.

When operating in Synchronous Rectification mode, the LDRV signal is held high until the beginning of the next switching cycle. At that time, the HDRV signal is asserted high, turning on the high-side MOSFET.

The PE1<DECON> bit controls the operating mode of the MCP19118/19.

6.13.2 HIGH-SIDE DRIVE STRENGTH
The peak source and sink current of the high-side driver can be configured to be either 1A source/sink or 2A source/sink. The PE1<REVSTR> bit determines the high-side drive strength.

6.13.3 MOSFET DRIVER DEAD TIME
As described in Section 6.9 “MOSFET Driver Programmable Dead Time”, the MOSFET driver dead time can be adjusted. In order to enable dead time settings, the proper bypass bits must be cleared. PE1<HDLYBY> and PE1<LDLYBY> control the delay circuits. Clearing the respective bits allows the dead time programmed by the DEADCON register to be added to the appropriate turn-on edge.

6.13.4 OUTPUT VOLTAGE SENSE PULL-UP/PULL-DOWN
A high-impedance pull-up on the +VSEN pin can be configured by setting the PE1<PUEN> bit. When set, the +VSEN pin is internally pulled-up to VDD.

A high-impedance pull-down on the -VSEN can be configured by setting the PE1<PDEN> bit. When set, the -VSEN pin is internally pulled-down to ground.

6.13.5 OUTPUT UNDERRIGHTAGE ACCELERATOR
The MCP19118/19 has additional control circuitry to allow it to respond quickly to an output undervoltage condition. The enabling of this circuitry is handled by the PE1<UVTEE> bit. When this bit is set, the MCP19118/19 will respond to an output undervoltage condition by setting both the HDRV and LDRV signals low and turning off both the high-side and low-side MOSFETs.

6.13.6 OUTPUT OVERTENSION ACCELERATOR
The MCP19118/19 has additional control circuitry to allow it to respond quickly to an output overvoltage condition. The enabling of this circuitry is handled by the PE1<OVTEE> bit. When this bit is set, the MCP19118/19 will respond to an output overvoltage condition by setting both the HDRV and LDRV signals low and turning off both the high-side and low-side MOSFETs.

6.14 Analog Blocks Enable Control

Various analog circuit blocks can be enabled or disabled, as shown in Register 6-15. Additional enable bits are located in the ATSTCON register.

6.14.1 OUTPUT OVERVOLTAGE ENABLE

The output overvoltage is enabled by setting the ABECON<OVDCEN> bit. Clearing this bit will disable the output overvoltage circuitry and cause the setting in the OOVCON register to be ignored.

6.14.2 OUTPUT UNDervoltage ENABLE

The output undervoltage is enabled by setting the ABECON<UVDCEN> bit. Clearing this bit will disable the output undervoltage circuitry and cause the setting in the OUVCON register to be ignored.

6.14.3 RELATIVE EFFICIENCY MEASUREMENT CONTROL

Section 10.0 “Relative Efficiency Measurement” describes the procedure used to measure the relative efficiency of the system. Setting the ABECON<MEASEN> bit initiates the relative measurement.

6.14.4 SLOPE COMPENSATION CONTROL

The slope compensation described in Register 6-7 can be bypassed by setting the ABECON<SLCPBY> bit. Under normal operation, this bit will always be set.

6.14.5 CURRENT MEASUREMENT CONTROL

The peak current measurement circuitry is controlled by the ABECON<CRTMEN> bit. Setting this bit enables the current measurement circuitry. Under normal operation, this bit will be set.

6.14.6 INTERNAL TEMPERATURE MEASUREMENT CONTROL

The internal temperature of the silicon can be measured with the ADC. To enable the internal temperature measurement circuitry, the ABECON<TMPSEN> bit must be set.

6.14.7 RELATIVE EFFICIENCY CIRCUITY CONTROL

Section 10.0 “Relative Efficiency Measurement” describes the procedure used to measure the relative efficiency of the system. Setting the ABECON<RECIREN> bit enables the relative efficiency measurement circuitry.

6.14.8 SIGNAL CHAIN CONTROL

Setting the ABECON<PATHEN> bit enables the voltage control path. Under normal operation, this bit is set.

8.0  SYSTEM BENCH TESTING

To allow for easier system design and bench testing, the MCP19118/19 family of devices features a multiplexer used to output various internal analog signals. These signals can be measured on the GPA0 pin through a unity gain buffer. The configuration control of the GPA0 pin is found in the ATSTCON register.

Control of the signals present at the output of the unity gain buffer is found in the BUFFCON register.

8.1  Analog Bench Test Control

8.1.1  ATSTCON REGISTER

The ATSTCON register contains the bits used to disable the MOSFET drivers and configure the GPA0 pin as the unity gain buffer out.

Note 1: The DRVDIS bit is reset to ‘1’ so the high-side and low-side drivers are in a known state after reset. This bit must be cleared by software for normal operation.

2: For proper operation, bit 7 must always be set to ‘1’.

bit 0  DRVDIS: MOSFET driver disable control bit
1 = High-side and low-side drivers are set low, PHASE pin is floating
0 = High-side and low-side drivers are set for normal operation
8.2 Unity Gain Buffer

The unity gain buffer module is used during a multi-phase application and while operating in Bench Test mode.

When the ATSTCON<BNCHEN> bit is set, the device is in Bench Test mode and the ASEL<4:0> bits in the BUFFCON register determine which internal analog signal can be measured on the GPA0 pin.

When measuring signals with the unity gain buffer, the buffer offset must be added to the measured signal. The factory-measured buffer offset can be read from memory location 2087h. Refer to Section 11.1.1 “Reading Program Memory as Data” for more information.

### 9.0 DEVICE CALIBRATION

Read-only memory locations 2080h through 208Fh contain factory calibration data. Refer to Section 18.0 “Flash Program Memory Control” for information on how to read from these memory locations.

### 9.1 Calibration Word 1

The DOV<3:0> bits at memory location 2080h set the offset calibration for the output voltage remote sense differential amplifier. Firmware must read these values and write them to the DOVCAL register for proper calibration.

The FCAL<6:0> bits at memory location 2080h set the internal oscillator calibration. Firmware must read these values and write them to the OSCCAL register for proper calibration.

9.4 Calibration Word 4 and Calibration Word 5

The data stored in the CALWD4 and CALWD5 registers can be used by firmware to provide a more accurate internal temperature sensor ADC reading. The coefficients for a straight line equation can be generated by manipulation of the values stored in these calibration words. These calibration words contain all gains and offsets associated with reading the input voltage with the internal ADC.

9.4.1 CALWD4: INTERNAL TEMPERATURE READING GAIN TERM

The CALWD4 register is located at program memory location 2083h and represents the coefficient, Z, used in Equation 9-1. This coefficient is used to calculate the gain of the internal temperature reading by the ADC.

\[
m = Z \times 2^N
\]

Where:
- \(m\) = gain
- \(Z\) = 14-bit integer
- \(N = 12\)

9.4.2 CALWD5: INTERNAL TEMPERATURE READING OFFSET VOLTAGE TERM

The CALWD5 register is located at program memory location 2084h and represents the coefficient, W, used in Equation 9-2. This coefficient is used to calculate the offset voltage of the internal temperature reading by the ADC.

\[
b = W \times 2^N
\]

Where:
- \(b\) = offset voltage
- \(W\) = 14-bit two's complement integer
- \(N = 4\)

9.5 Calibration Word 6 and Calibration Word 7

The MCP19118/19 has the ability to read and report the system input voltage. Firmware can be written that uses the data stored in the CALWD6 and CALWD7 registers to improve the accuracy of this voltage reading. These calibration words contain the gain and offset voltage associated with reading the input voltage with ADC.

9.5.1 CALWD6: INPUT VOLTAGE READING GAIN TERM

The data stored in the CALWD6 register at program memory location 2085h is an 8-bit number that represents the coefficient, Z, used in Equation 9-3. This coefficient is used to calculate the gain of the input voltage ADC reading circuitry.

\[
m = \frac{1}{Z} \times 2^N
\]

Where:

- \( m \) = gain
- \( Z \) = 8-bit integer
- \( N \) = 11

9.5.2 CALWD7: INPUT VOLTAGE READING OFFSET VOLTAGE

The data stored in the CALWD7 register at program memory location 2086h is an 8-bit two’s complement integer that represents the offset voltage of the input voltage reading circuitry.

10.0 RELATIVE EFFICIENCY MEASUREMENT

With a constant input voltage, output voltage and load current, any change in the high-side MOSFET on time represents a change in the system efficiency. The MCP19118/19 is capable of measuring the on time of the high-side MOSFET. Therefore, the relative efficiency of the system can be measured and optimized by changing the system parameters, such as switching frequency, driver dead time or high-side drive strength.

10.1 Relative Efficiency Measurement Procedure

To measure the relative efficiency, the RELEFF register, the ABECON<MEASEN> and ABECON<RECIREN> bits and the ADC RELEFF input are used. The following steps outline the measurement process:

1. Set the ABECON<RECIREN> bit to enable the measurement circuitry.
2. Clear the ABECON<MEASEN> bit.
3. With the ADC, read the RELEFF channel and store this reading as the High.
4. With the ADC, read the VZC channel and store this reading as the Low.
5. Set the ABECON<MEASEN> bit to initiate a measurement cycle.
6. Monitor the RELEFF<MSDONE> bit. When set, it indicates the measurement is complete.
7. When the measurement is complete, use the ADC to read the RELEFF channel. This value becomes the Fractional variable in Equation 10-1. This reading should be accomplished approximately 50 ms after the RELESS<MSDONE> bit is set.
8. Read the value of the RE<6:0> bits in the RELEFF register and store the reading as Whole.
9. Clear the ABECON<MEASEN> bit.
10. The relative efficiency is then calculated by the following equation:

EQUATION 10-1:

\[
\text{Duty Cycle} = \frac{\text{Whole} + (\text{Fractional} - \text{Low})}{(\text{High} - \text{Low})} \cdot \frac{1}{PR2 + 1}
\]

Where:
- \(\text{Whole}\) = Value obtained in Step 8 of the measurement procedure
- \(\text{Fractional}\) = Value obtained in Step 7 of the measurement procedure
- \(\text{High}\) = Value obtained in Step 3 of the measurement procedure
- \(\text{Low}\) = Value obtained in Step 4 of the measurement procedure

Note 1: The RELEFF<MSDONE> bit is set and cleared automatically.

bit 6-0
- RE<6:0>: Whole clock counts for relative efficiency measurement result
11.0 MEMORY ORGANIZATION

There are two types of memory in the MCP19118/19:
- Program Memory
- Data Memory
  - Special Function Registers (SFRs)
  - General Purpose RAM

11.1 Program Memory Organization

The MCP19118/19 has a 13-bit program counter capable of addressing an 8K x 14 program memory space. Only the first 4K x 14 (0000h-0FFFh) is physically implemented. Addressing a location above this boundary will cause a wrap-around within the first 4K x 14 space. The Reset vector is at 0000h and the interrupt vector is at 0004h (see Figure 11-1). The width of the program memory bus (instruction word) is 14 bits. Since all instructions are a single word, the MCP19118/19 has space for 4K of instructions.
11.1.1 READING PROGRAM MEMORY AS DATA

There are two methods of accessing constants in program memory. The first method is to use tables of RETLW instructions. The second method is to set a Files Select Register (FSR) to point to the program memory.

11.1.1.1 RETLW Instruction

The RETLW instruction can be used to provide access to tables of constants. The recommended way to create such a table is shown in Example 11-1.

**EXAMPLE 11-1: RETLW INSTRUCTION**

```asm
EXAMPLE 11-1:
RETLW DATA0 ; Index0 data
RETLW DATA1 ; Index1 data
RETLW DATA2
RETLW DATA3
```

The STATUS register can be the destination for any instruction, like any other register. If the STATUS register is the destination for an instruction that affects the Z, DC or C bits, then the write to these three bits is disabled. These bits are set or cleared according to the device logic. Furthermore, the TO and PD bits are not writable. Therefore, the result of an instruction with the STATUS register as destination may be different than intended.

For example, CLRF STATUS will clear the upper three bits and set the Z bit. This leaves the STATUS register as `'000u uluu'` (where `u = unchanged`).

Therefore, it is recommended that only BCF, BSF, SWAPF and MOVWF instructions are used to alter the STATUS register, because these instructions do not affect any Status bits. For other instructions not affecting any Status bits, see Section 29.0 “Instruction Set Summary”.

**Note 1:** The C and DC bits operate as Borrow and Digit Borrow out bits, respectively, in subtraction.

### 11.2 Data Memory Organization

The data memory (see Table 11-1) is partitioned into four banks, which contain the General Purpose Registers (GPR) and the Special Function Registers (SFR). The Special Function Registers are located in the first 32 locations of each bank. Register locations 20h-7Fh in Bank 0, A0h-EFh in Bank 1 and 120h-16Fh in Bank 2 are General Purpose Registers, implemented as static RAM. All other RAM is unimplemented and returns `'0'` when read. The RP<1:0> bits in the STATUS register are the bank select bits.

#### RP1 RP0

<table>
<thead>
<tr>
<th>Value</th>
<th>Bank</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 0</td>
<td>Bank 0 is selected</td>
</tr>
<tr>
<td>0 1</td>
<td>Bank 1 is selected</td>
</tr>
<tr>
<td>1 0</td>
<td>Bank 2 is selected</td>
</tr>
<tr>
<td>1 1</td>
<td>Bank 3 is selected</td>
</tr>
</tbody>
</table>

To move values from one register to another, the value must pass through the W register. This means that, for all register-to-register moves, two instruction cycles are required.

The STATUS register contains:

- the arithmetic status of the ALU (Arithmetic Logic Unit)
- the Reset status
- the bank select bits for data memory (RAM)
11.2.1 SPECIAL FUNCTION REGISTERS

The Special Function Registers are registers used by the CPU and peripheral functions for controlling the desired operation of the device (see Table 11-1). These registers are static RAM.

The special registers can be classified into two sets: core and peripheral. The Special Function Registers associated with the microcontroller core are described in this section. Those related to the operation of the peripheral features are described in the associated section for that peripheral feature.

**Legend:**
- = Unimplemented locations read as '0', u = unchanged, x = unknown, q = value depends on condition, shaded = unimplemented

**Note:**
1. Other (non power-up) resets include MCLR Reset and Watchdog Timer Reset during normal operation.
2. IRP & RPI bits are reserved, always maintain these bits clear.
3. RA3 pull-up is enabled when pin is configured as MCLR in Configuration Word.
4. MCLR and WDT Reset does not affect the previous value data latch. The IOCF bit will be cleared upon reset but will set again if the mismatch exists.
5. Only accessible when DBGEN = 0 and ICKBUG<INBUG> = 1.
11.3.1 OPTION_REG REGISTER

The OPTION_REG register is a readable and writable register, which contains various control bits to configure:

- Timer0/WDT prescaler
- External GPA2/INT interrupt
- Timer0
- Weak pull-ups on PORTGPA and PORTGPB

**Note 1:** To achieve a 1:1 prescaler assignment for Timer0, assign the prescaler to the WDT by setting PSA bit in the OPTION_REG register to ‘1’. See Section 23.1.3 “Software-Programmable Prescaler”.

**Note 1:** Individual WPUx bit must also be enabled.
11.4 PCL and PCLATH

The Program Counter (PC) is 13-bit wide. The low byte comes from the PCL register, which is a readable and writable register. The high byte (PC<12:8>) is not directly readable or writable and comes from PCLATH. On any Reset, the PC is cleared. Figure 11-2 shows the two situations for loading the PC. The upper example in Figure 11-2 shows how the PC is loaded on a write to PCL (PCLATH<4:0> → PCH). The lower example in Figure 11-2 shows how the PC is loaded during a CALL or GOTO instruction (PCLATH<4:3> → PCH).

11.4.1 MODIFYING PCL

Executing any instruction with the PCL register as the destination simultaneously causes the Program Counter PC<12:8> bits (PCH) to be replaced by the contents of the PCLATH register. This allows the entire content of the program counter to be changed by writing the desired upper five bits to the PCLATH register. When the lower eight bits are written to the PCL register, all 13 bits of the program counter will change to the values contained in the PCLATH register and those being written to the PCL register.

11.4.2 COMPUTED GOTO

A computed GOTO is accomplished by adding an offset to the program counter (ADDF PCL). Care should be exercised when jumping into a look-up table or program branch table (computed GOTO) by modifying the PCL register. Assuming that PCLATH is set to the table start address, if the table length is greater than 255 instructions or if the lower eight bits of the memory address rolls over from 0xFFh to 0X00h in the middle of the table, then PCLATH must be incremented for each address rollover that occurs between the table beginning and the table location within the table.

For more information, refer to Application Note AN556 – “Implementing a Table Read” (DS00556).

11.4.3 COMPUTED FUNCTION CALLS

A computed function CALL allows programs to maintain tables of functions and provides another way to execute state machines or look-up tables. When performing a table read using a computed function CALL, care should be exercised if the table location crosses a PCL memory boundary (each 256-byte block).

If using the CALL instruction, the PCH<2:0> and PCL registers are loaded with the operand of the CALL instruction. PCH<6:3> is loaded with PCLATH<6:3>.

11.4.4 STACK

The MCP19118/19 has an 8-level x 13-bit wide hardware stack (refer to Figure 11-1). The stack space is not part of either program or data space and the Stack Pointer is not readable or writable. The PC is PUSHed onto the stack when a CALL instruction is executed or an interrupt causes a branch. The stack is POPed in the event of a RETURN, RETLW or a RETFIE instruction execution. PCLATH is not affected by a PUSH or POP operation.

The stack operates as a circular buffer. This means that after the stack has been PUSHed eight times, the ninth push overwrites the value that was stored from the first push. The tenth push overwrites the second push (and so on).

Note 1: There are no Status bits to indicate Stack Overflow or Stack Underflow conditions.

2: There are no instructions/mnemonics called PUSH or POP. These are actions that occur from the execution of the CALL, RETURN, RETLW and RETFIE instructions or the vectoring to an interrupt address.

11.5 Indirect Addressing, INDF and FSR Registers

The INDF register is not a physical register. Addressing the INDF register will cause indirect addressing.

Indirect addressing is possible by using the INDF register. Any instruction using the INDF register actually accesses data pointed to by the File Select Register (FSR). Reading INDF itself indirectly will produce 00h. Writing to the INDF register directly results in no operation being performed (although Status bits may be affected). An effective 9-bit address is obtained by concatenating the 8-bit FSR and the IRP bit in the STATUS register, as shown in Figure 11-3.

A simple program to clear RAM location 40h-7Fh using indirect addressing is shown in Example 11-2.
EXAMPLE 11-2: INDIRECT ADDRESSING

MOVLW 0x40  ;initialize pointer
MOVWF FSR   ;to RAM
NEXT CLRF INDF ;clear INDF register
INCF FSR  ;inc pointer
BTFSS FSR,7  ;all done?
GOTO NEXT  ;no clear next
CONTINUE    ;yes continue

12.0 DEVICE CONFIGURATION

Device Configuration consists of Configuration Word and Code Protection.

12.1 Configuration Word

There are several Configuration Word bits that allow different timers to be enabled and memory protection options. These are implemented as Configuration Word at 2007h.

Note: The DBGEN bit in Configuration Word is managed automatically by device development tools, including debuggers and programmers. For normal device operation, this bit should be maintained as a ‘1’.

‘0’ = Bit is cleared
x = Bit is unknown
12.2 Code Protection

Code protection allows the device to be protected from unauthorized access. Internal access to the program memory is unaffected by any code protection setting.

12.2.1 PROGRAM MEMORY PROTECTION

The entire program memory space is protected from external reads and writes by the CP bit in the Configuration Word. When CP = 0, external reads and writes of the program memory are inhibited and a read will return all '0's. The CPU can continue to read program memory, regardless of the protection bit settings. Writing the program memory is dependent upon the write protection setting. See Section 12.3 “Write Protection” for more information.

12.3 Write Protection

Write protection allows the device to be protected from unintended self-writes. Applications, such as bootloader software, can be protected while allowing other regions of the program memory to be modified.

The WRT<1:0> bits in the Configuration Word define the size of the program memory block that is protected.

12.4 ID Locations

Four memory locations (2000h-2003h) are designated as ID locations where the user can store checksum or other code identification numbers. These locations are not accessible during normal execution but are readable and writable during Program/Verify mode. Only the Least Significant seven bits of the ID locations are reported when using MPLAB Integrated Development Environment (IDE).
13.0 OSCILLATOR MODES

The MCP19118/19 has one oscillator configuration which is an 8 MHz internal oscillator.

13.1 Internal Oscillator (INTOSC)

The Internal Oscillator module provides a system clock source of 8 MHz. The frequency of the internal oscillator can be trimmed with a calibration value in the OSCTUNE register.

13.2 Oscillator Calibration

The 8 MHz internal oscillator is factory-calibrated. The factory calibration values reside in the read-only Calibration Word 1 register. These values must be read from the Calibration Word 1 register and stored in the OSCCAL register. Refer to Section 18.0 “Flash Program Memory Control” for the procedure on reading from program memory.

Note 1: The FCAL<6:0> bits from the Calibration Word 1 register must be written into the OSCCAL register to calibrate the internal oscillator.

011110 =
  
  
  
  
  00011 =
00000 = Center frequency. Oscillator Module is running at the calibrated frequency.
11111 =
  
  
  
  10000 = Minimum frequency

13.3 Frequency Tuning in User Mode

In addition to the factory calibration, the base frequency can be tuned in the user's application. This frequency tuning capability allows the user to deviate from the factory-calibrated frequency. The user can tune the frequency by writing to the OSCTUNE register (Register 13-1).
13.3.1 OSCILLATOR DELAY UPON POWER-UP, WAKE-UP AND BASE FREQUENCY CHANGE

In applications where the OSCTUNE register is used to shift the frequency of the internal oscillator, the application should not expect the frequency of the internal oscillator to stabilize immediately. In this case, the frequency may shift gradually toward the new value. The time for this frequency shift is less than eight cycles of the base frequency.

On power-up, the device is held in reset by the power-up time, if the power-up timer is enabled. Following a wake-up from Sleep mode or POR, an internal delay of ~10 µs is invoked to allow the memory bias to stabilize before program execution can begin.

14.0 RESETS

The reset logic is used to place the MCP19118/19 into a known state. The source of the reset can be determined by using the device status bits.

There are multiple ways to reset this device:
- Power-On Reset (POR)
- Overtemperature Reset (OT)
- MCLR Reset
- WDT Reset

To allow $V_{DD}$ to stabilize, an optional power-up timer can be enabled to extend the Reset time after a POR event.

Some registers are not affected in any Reset condition; their status is unknown on POR and unchanged in any other Reset. Most other registers are reset to a Reset state on:
- Power-On Reset
- MCLR Reset
- MCLR Reset during Sleep
- WDT Reset

WDT wake-up does not cause register resets in the same manner as a WDT Reset, since wake-up is viewed as the resumption of normal operation. TO and PD bits are set or cleared differently in different Reset situations, as indicated in Table 14-1. Software can use these bits to determine the nature of the Reset. See Table 14-2 for a full description of Reset states of all registers.

A simplified block diagram of the On-Chip Reset Circuit is shown in Figure 14-1.

The MCLR Reset path has a noise filter to detect and ignore small pulses. See Section 5.0 “Digital Electrical Characteristics” for pulse width specifications.

FIGURE 14-1: SIMPLIFIED BLOCK DIAGRAM OF ON-CHIP RESET CIRCUIT

![Simplified block diagram of the On-Chip Reset Circuit]

</thead>
<tbody>
<tr>
<td>Power-Up</td>
</tr>
<tr>
<td>----------</td>
</tr>
<tr>
<td>PWRT = 0</td>
</tr>
<tr>
<td>$T_{PWRT}$</td>
</tr>
</tbody>
</table>
14.1 Power-On Reset (POR)

The on-chip POR circuit holds the chip in Reset until VDD has reached a high enough level for proper operation. To take advantage of the POR, simply connect the MCLR pin through a resistor to VDD. This will eliminate external RC components usually needed to create Power-On Reset.

Note: The POR circuit does not produce an internal Reset when VDD declines. To re-enable the POR, VDD must reach VSS for a minimum of 100 µs.

When the device starts normal operation (exits the Reset condition), device operating parameters (i.e., voltage, frequency, temperature, etc.) must be met to ensure proper operation. If these conditions are not met, the device must be held in Reset until the operating conditions are met.

14.2 MCLR

MCP19118/19 has a noise filter in the MCLR Reset path. The filter will detect and ignore small pulses.

It should be noted that a WDT Reset does not drive MCLR pin low.

Voltages applied to the MCLR pin that exceed its specification can result in both MCLR Resets and excessive current beyond the device specification during the ESD event. For this reason, Microchip recommends that the MCLR pin no longer be tied directly to VDD. The use of an RC network, as shown in Figure 14-2, is suggested.

An internal MCLR option is enabled by clearing the MCLRE bit in the Configuration Word register. When MCLRE = 0, the Reset signal to the chip is generated internally. When MCLRE = 1, the MCLR pin becomes an external Reset input. In this mode, the MCLR pin has a weak pull-up to VDD.

FIGURE 14-2: RECOMMENDED MCLR CIRCUIT

![Recommended MCLR Circuit](image)
14.3 Power-Up Timer (PWRT)

The Power-Up Timer provides a fixed 64 ms (nominal) time out on power-up only, from POR Reset. The Power-Up Timer operates from an internal RC oscillator. The chip is kept in Reset as long as PWRT is active. The PWRT delay allows the $V_{DD}$ to rise to an acceptable level. A Configuration bit, PWRTE, can disable (if set) or enable (if cleared or programmed) the Power-Up Timer.

The Power-Up Timer delay will vary from chip to chip due to:
- $V_{DD}$ variation
- Temperature variation
- Process variation

**Note:** Voltage spikes below $V_{SS}$ at the MCLR pin, inducing currents greater than 80 mA, may cause latch-up. Thus, a series resistor of 50-100 $\Omega$ should be used when applying a “low” level to the MCLR pin, rather than pulling this pin directly to $V_{SS}$.

14.4 Watchdog Timer (WDT) Reset

The Watchdog Timer generates a Reset if the firmware does not issue a CLRWDT instruction within the time-out period. The TO and PD bits in the STATUS register are changed to indicate the WDT Reset. See Section 17.0 “Watchdog Timer (WDT)” for more information.

14.5 Power-Up Timer

The Power-Up Timer optionally delays device execution after a POR event. This timer is typically used to allow $V_{DD}$ to stabilize before allowing the device to start running.

The Power-Up Timer is controlled by the PWRTE bit of Configuration Word.

14.6 Start-Up Sequence

Upon the release of a POR, the following must occur before the device begins executing:
- Power-Up Timer runs to completion (if enabled)
- Oscillator start-up timer runs to completion
- MCLR must be released (if enabled)

The total time out will vary based on the PWRTE bit status. For example, with PWRTE bit erased (PWRT disabled), there will be no time out at all. Figures 14-3, 14-4 and 14-5 depict time-out sequences.

Since the time outs occur from the POR pulse, if MCLR is kept low long enough, the time outs will expire. Then, bringing MCLR high will begin execution immediately (see Figure 14-4). This is useful for testing purposes or to synchronize more than one MCP19118/19 device operating in parallel.

14.6.1 POWER CONTROL (PCON) REGISTER

The Power Control (PCON) register (address 8Eh) has two Status bits to indicate what type of Reset occurred last.

**Legend:**  
- **u** = unchanged,  
- **x** = unknown,  
- **-** = unimplemented bit, reads as '0',  
- **q** = value depends on condition.  

**Note:**  
1. If \( V_{DD} \) goes too low, Power-On Reset will be activated and registers will be affected differently.  
2. One or more bits in the INTCON and/or PIRx registers will be affected (to cause wake-up).  
3. When the wake-up is due to an interrupt and the GIE bit is set, the PC is loaded with the interrupt vector (0004h).  
4. See Table 14-5 for Reset value for specific condition.
14.7 Determining the Cause of a Reset

Upon any Reset, multiple bits in the STATUS and PCON registers are updated to indicate the cause of the Reset. Tables 14-4 and 14-5 show the Reset conditions of these registers.

Legend: — = unimplemented bit, reads as ‘0’. Shaded cells are not used by Resets.

Note 1: Other (non Power-Up) Resets include MCLR Reset and Watchdog Timer Reset during normal operation.
15.0 INTERRUPTS

The MCP19118/19 has multiple sources of interrupt:

- External Interrupt (INT pin)
- Interrupt-On-Change (IOC) Interrupts
- Timer0 Overflow Interrupt
- Timer1 Overflow Interrupt
- Timer2 Match Interrupt
- ADC Interrupt
- System Overvoltage Error
- System Undervoltage Error
- System Overcurrent Error
- SSP
- BCL
- System Input Undervoltage Error

The Interrupt Control (INTCON) register and Peripheral Interrupt Request (PIRx) registers record individual interrupt requests in flag bits. The INTCON register also has individual and global interrupt enable bits. The Global Interrupt Enable (GIE) bit in the INTCON register enables (if set) all unmasked interrupts or disables (if cleared) all interrupts. Individual interrupts can be disabled through their corresponding enable bits in the INTCON register and PIEx registers. GIE is cleared on Reset.

When an interrupt is serviced, the following actions occur automatically:

- The GIE is cleared to disable any further interrupt.
- The return address is pushed onto the stack.
- The PC is loaded with 0004h.

The firmware within the Interrupt Service Routine (ISR) should determine the source of the interrupt by polling the interrupt flag bits. The interrupt flag bits must be cleared before exiting the ISR, to avoid repeated interrupts. Because the GIE bit is cleared, any interrupt that occurs while executing the ISR will be recorded through its interrupt flag, but will not cause the processor to redirect to the interrupt vector.

15.1 Interrupt Latency

For external interrupt events, such as the INT pin or PORTGPx change interrupt, the interrupt latency will be three or four instruction cycles. The exact latency depends upon when the interrupt event occurs (see Figure 15-2). The latency is the same for one or two-cycle instructions.

15.2 GPA2/INT Interrupt

The external interrupt on the GPA2/INT pin is edge-triggered either on the rising edge, if the INTEDG bit in the OPTION_REG register is set or on the falling edge, if the INTEDG bit is cleared. When a valid edge appears on the GPA2/INT pin, the INTF bit in the INTCON register is set. This interrupt can be disabled by clearing the INTE control bit in the INTCON register. The INTF bit must be cleared by software in the Interrupt Service Routine before re-enabling this interrupt. The GPA2/INT interrupt can wake-up the processor from Sleep, if the INTE bit was set prior to going into Sleep. See Section 16.0 “Power-Down Mode (Sleep)” for details on Sleep and Section 16.1 “Wake-Up from Sleep” for timing of wake-up from Sleep through GPA2/INT interrupt.

Note: The ANSELx registers must be initialized to configure an analog channel as a digital input. Pins configured as analog inputs will read ‘0’ and cannot generate an interrupt.

Note 1: Individual interrupt flag bits are set, regardless of the status of their corresponding mask bit or the GIE bit.

2: When an instruction that clears the GIE bit is executed, any interrupts that were pending for execution in the next cycle are ignored. The interrupts which were ignored are still pending to be serviced when the GIE bit is set again.

The RETFIE instruction exits the ISR by popping the previous address from the stack, restoring the saved context from the shadow registers and setting the GIE bit.

For additional information on a specific Interrupt’s operation, refer to its Peripheral chapter.
FIGURE 15-1: INTERRUPT LOGIC

FIGURE 15-2: INT PIN INTERRUPT TIMING

Note 1: INTF flag is sampled here (every Q1).

2: Asynchronous interrupt latency = 3-4 T_{CY}. Synchronous latency = 3 T_{CY}, where T_{CY} = instruction cycle time. Latency is the same whether Inst (PC) is a single cycle or a two-cycle instruction.

3: CLKOUT is available only in INTOSC and RC Oscillator modes.

4: For minimum width of INT pulse, refer to the AC specifications in Section 5.0 “Digital Electrical Characteristics”.

5: INTF is enabled to be set any time during the Q4–Q1 cycles.
### 15.3 Interrupt Control Registers

#### 15.3.1 INTCON REGISTER

The INTCON register is a readable and writable register that contains the various enable and flag bits for the TMR0 register overflow, interrupt-on-change and external INT pin interrupts.

**Note:** Interrupt flag bits are set when an interrupt condition occurs, regardless of the state of its corresponding enable bit or the Global Interrupt Enable (GIE) bit in the INTCON register. User software should ensure the appropriate interrupt flag bits are clear prior to enabling an interrupt.

**REGISTER 15-1: INTCON: INTERRUPT CONTROL REGISTER**

- **bit 2**
  - **T0IF**: TMR0 Overflow Interrupt Flag bit(2)
    - 1 = TMR0 register overflowed (must be cleared in software)
    - 0 = TMR0 register did not overflow

- **bit 1**
  - **INTF**: External Interrupt Flag bit
    - 1 = The external interrupt occurred (must be cleared in software)
    - 0 = The external interrupt did not occur

- **bit 0**
  - **IOCF**: Interrupt-on-Change Interrupt Flag bit
    - 1 = When at least one of the interrupt-on-change pins changed state
    - 0 = None of the interrupt-on-change pins changed state

**Note 1:** The IOCx registers must also be enabled.

**Note 2:** T0IF bit is set when TMR0 rolls over. TMR0 is unchanged on Reset and should be initialized before clearing T0IF bit.
15.3.1.1 PIE1 Register

The PIE1 register (Register 15-2) contains the Peripheral Interrupt Enable bits.

**Note 1:** The PEIE bit in the INTCON register must be set to enable any peripheral interrupt.

**Legend:** — = unimplemented locations read as ‘0’. Shaded cells are not used by Interrupts.
15.4 Context Saving During Interrupts

During an interrupt, only the return PC value is saved on the stack. Typically, users may wish to save key registers during an interrupt (e.g., W and STATUS registers). This must be implemented in software.

Temporary holding registers W_TEMP and STATUS_TEMP should be placed in the last 16 bytes of GPR (see Figure 11-2). These 16 locations are common to all banks and do not require banking. This makes context save and restore operations simpler.

The code shown in Example 15-1 can be used to:

- Store the W register
- Store the STATUS register
- Execute the ISR code
- Restore the Status (and Bank Select Bit) register
- Restore the W register

Note: The MCP19118/19 device does not require saving the PCLATH. However, if computed GOTOs are used in both the ISR and the main code, the PCLATH must be saved and restored in the ISR.

EXAMPLE 15-1: SAVING STATUS AND W REGISTERS IN RAM

```
MOVWF W_TEMP            ;Copy W to TEMP register
SWAPF STATUS,W          ;Swap status to be saved into W
                        ;Swaps are used because they do not affect the status bits
MOVWF STATUS_TEMP       ;Save status to bank zero STATUS_TEMP register
                        ;(ISR) ;Insert user code here
                        ;
SWAPF STATUS_TEMP,W     ;Swap STATUS_TEMP register into W
                        ;(sets bank to original state)
MOVWF STATUS            ;Move W into STATUS register
SWAPF W_TEMP,F          ;Swap W_TEMP
SWAPF W_TEMP,W          ;Swap W_TEMP into W
```
16.0 POWER-DOWN MODE (SLEEP)

The Power-Down mode is entered by executing a SLEEP instruction.

Upon entering Sleep mode, the following conditions exist:
1. WDT will be cleared but keeps running, if enabled for operation during Sleep.
2. The PD bit in the STATUS register is cleared.
3. The TO bit in the STATUS register is set.
4. CPU clock is not disabled.
5. The Timer1 oscillator is unaffected and peripherals that operate from it may continue operation in Sleep.
6. The ADC is unaffected.
7. The I/O ports maintain the status they had before SLEEP was executed (driving high, low or high-impedance).
8. Resets other than WDT are not affected by Sleep mode.
9. Analog circuitry is unaffected by execution of SLEEP instruction.

Refer to individual chapters for more details on peripheral operation during Sleep.

To minimize current consumption, the following conditions should be considered:
- I/O pins should not be floating
- External circuitry sinking current from I/O pins
- Internal circuitry sourcing current from I/O pins
- Current draw from pins with internal weak pull-ups
- Modules using Timer1 oscillator

I/O pins that are high-impedance inputs should be pulled to VDD or GND externally to avoid switching currents caused by floating inputs.

The SLEEP instruction does not affect the analog circuitry. The enable state of the analog circuitry does not change with the execution of the SLEEP instruction.

Examples of internal circuitry that might be sourcing current include modules, such as the DAC. See Section 22.0 “Analog-to-Digital Converter (ADC) Module” for more information on this module.

16.1 Wake-Up from Sleep

The device can wake-up from Sleep through one of the following events:
1. External Reset input on MCLR pin, if enabled
2. POR Reset
3. Watchdog Timer, if enabled
4. Any external interrupt
5. Interrupts by peripherals capable of running during Sleep (see individual peripheral for more information)

The first two events will cause a device Reset. The last three events are considered a continuation of program execution. To determine whether a device Reset or Wake-Up event occurred, refer to Section 14.7 “Determining the Cause of a Reset”.

The following peripheral interrupts can wake the device from Sleep:
1. Timer1 interrupt. Timer1 must be operating as an asynchronous counter.
2. A/D conversion
3. Interrupt-on-change
4. External Interrupt from the INT pin

When the SLEEP instruction is being executed, the next instruction (PC + 1) is prefetched. For the device to wake-up through an interrupt event, the corresponding interrupt enable bit must be enabled. Wake-up will occur regardless of the state of the GIE bit. If the GIE bit is disabled, the device continues execution at the instruction after the SLEEP instruction. If the GIE bit is enabled, the device executes the instruction after the SLEEP instruction, the device will then call the Interrupt Service Routine. In cases where the execution of the instruction following SLEEP is not desirable, the user should have an NOP after the SLEEP instruction.

The WDT is cleared when the device wakes up from Sleep, regardless of the source of wake-up.
### 16.1.1 WAKE-UP USING INTERRUPTS

When global interrupts are disabled (GIE cleared) and any interrupt source has both its interrupt enable bit and interrupt flag bit set, one of the following will occur:

- **If the interrupt occurs before the execution of a SLEEP instruction:**
  - SLEEP instruction will execute as an NOP
  - WDT and WDT prescaler will not be cleared
  - The TO bit in the STATUS register will not be set
  - The PD bit in the STATUS register will not be cleared

- **If the interrupt occurs during or after the execution of a SLEEP instruction:**
  - SLEEP instruction will be completely executed
  - The device will immediately wake-up from Sleep
  - WDT and WDT prescaler will be cleared
  - The TO bit in the STATUS register will be set
  - The PD bit in the STATUS register will be cleared

Even if the flag bits were checked before executing a SLEEP instruction, it may be possible for flag bits to become set before the SLEEP instruction completes. To determine whether a SLEEP instruction executed, test the PD bit. If the PD bit is set, the SLEEP instruction was executed as an NOP.

17.0 WATCHDOG TIMER (WDT)

The Watchdog Timer is a free-running timer. The WDT is enabled by setting the WDTE bit in the Configuration Word (default setting).

During normal operation, a WDT time out generates a device Reset. If the device is in Sleep mode, a WDT time out causes the device to wake-up and continue with normal operation.

The WDT can be permanently disabled by clearing the WDTE bit in the Configuration Word register. See Section 12.1 “Configuration Word” for more information.

17.1 Watchdog Timer (WDT) Operation

During normal operation, a WDT time out generates a device Reset. If the device is in Sleep mode, a WDT time out causes the device to wake-up and continue with normal operation; this is known as a WDT wake-up. The WDT can be permanently disabled by clearing the WDTE configuration bit.

The postscaler assignment is fully under software control and can be changed during program execution.

17.2 WDT Period

The WDT has a nominal time-out period of 18 ms (with no prescaler). The time-out periods vary with temperature, VDD and process variations from part to part (see Table 5-4). If longer time-out periods are desired, a prescaler with a division ratio of up to 1:128 can be assigned to the WDT under software control by writing to the OPTION_REG register. Thus, time-out periods up to 2.3 seconds can be realized.

The CLRWDT and SLEEP instructions clear the WDT and the prescaler, if assigned to the WDT, and prevent it from timing out and generating a device Reset.

The TO bit in the STATUS register will be cleared upon a Watchdog Timer time out.

17.3 WDT Programming Considerations

Under worst-case conditions (i.e., VDD = Minimum, Temperature = Maximum, Maximum WDT prescaler), it may take several seconds before a WDT time out occurs.

18.0 FLASH PROGRAM MEMORY CONTROL

The Flash program memory is readable and writable during normal operation (full \( V_{IN} \) range). This memory is not directly mapped in the register file space. Instead, it is indirectly addressed through the Special Function Registers (SFR) (see Registers 18-1 to 18-5). There are six SFRs used to read and write this memory:

- PMCON1
- PMCON2
- PMDATL
- PMDATH
- PMADRL
- PMADRH

When interfacing the program memory block, the PMDATL and PMDATH registers form a two-byte word, which holds the 14-bit data for read/write, while the PMADRL and PMADRH registers form a two-byte word, which holds the 13-bit address of the FLASH location being accessed. These devices have 4K words of program Flash with an address range from 0000h to 0FFFh.

The program memory allows single-word read and a four-word write. A four-word write automatically erases the row of the location and writes the new data (erase before write).

The write time is controlled by an on-chip timer. The write/erase voltages are generated by an on-chip charge pump rated to operate over the voltage range of the device for byte or word operations.

When the device is code-protected, the CPU may continue to read and write the Flash program memory. Depending on the settings of the Flash Program Memory Enable (WRT<1:0>) bits, the device may or may not be able to write certain blocks of the program memory. However, reads of the program memory are allowed.

When the Flash Program Memory Code Protection (CP) bit is enabled, the program memory is code-protected and the device programmer (ICSP) cannot access data or program memory.

18.1 PMADRH and PMADRL Registers

The PMADRH and PMADRL registers can address up to a maximum of 4K words of program memory.

When selecting a program address value, the Most Significant Byte (MSB) of the address is written to the PMADRH register and the Least Significant Byte (LSB) is written to the PMADRL register.

18.2 PMCON1 and PMCON2 Registers

PMCON1 is the control register for the data program memory accesses.

Control bits RD and WR initiate read and write, respectively. These bits cannot be cleared, only set in software. They are cleared in hardware at completion of the read or write operation. The inability to clear the WR bit in software prevents the accidental premature termination of a write operation.

The WREN bit, when set, will allow a write operation. On power-up, the WREN bit is clear.

The CALSEL bit allows the user to read locations in test memory in case there are calibration bits stored in the calibration word locations that need to be transferred to SFR trim registers. The CALSEL bit is only for reads and, if a write operation is attempted with CALSEL = 1, no write will occur.

PMCON2 is not a physical register. Reading PMCON2 will read all 0's. The PMCON2 register is used exclusively in the flash memory write sequence.

0 = Write cycle to the Flash memory is complete

bit 0 RD: Read Control bit
1 = Initiates a program memory read. (The read takes one cycle. The RD is cleared in hardware; the RD bit can only be set (not cleared) in software.)
0 = Does not initiate a Flash memory read
18.3.1 READING THE FLASH PROGRAM MEMORY

To read a program memory location, the user must write two bytes of the address to the PMADRL and PMADRH registers and then set control bit RD (PMCON1<0>). Once the read control bit is set, the program memory Flash controller will use the second instruction cycle after setting the control bit to read the data. This causes the second instruction immediately following the "BSF PMCON1,RD" instruction to be ignored. The data is available, in the very next cycle, in the PMDATL and PMDATH registers; it can be read as two bytes in the following instructions. PMDATL and PMDATH registers will hold this value until another read or until it is written to by the user (during a write operation).

EXAMPLE 18-1: FLASH PROGRAM READ

```

MOVFPMDATL, W; W = LS Byte of Program PMDATL
MOVFPMDATL, W; W = MS Byte of Program PMDATL
```

FIGURE 18-1: FLASH PROGRAM MEMORY READ CYCLE EXECUTION – NORMAL MODE
18.3.2 WRITING TO THE FLASH PROGRAM MEMORY

A word of the Flash program memory may only be written to if the word is in an unprotected segment of memory, as defined in Section 12.1 “Configuration Word” (bits WRT<1:0>).

**Note:** The write-protect bits are used to protect the users’ program from modification by the user's code. They have no effect when programming is performed by ICSP. The code-protect bits, when programmed for code protection, will prevent the program memory from being written via the ICSP interface.

Flash program memory must be written in four-word blocks. See Figures 18-2 and 18-3 for more details. A block consists of four words with sequential addresses, with a lower boundary defined by an address, where PMADRL<1:0> = 00. All block writes to program memory are done as 16-word erase by four-word write operations. The write operation is edge-aligned and cannot occur across boundaries.

To write program data, the WREN bit must be set and the data must first be loaded into the buffer registers (see Figure 18-2). This is accomplished by first writing the destination address to PMADRL and PMADRH and then writing the data to PMDATL and PMDATH. After the address and data have been set, the following sequence of events must be executed:

1. Write 55h, then AAh, to PMCON2 (Flash programming sequence).
2. Set the WR control bit in the PMCON1 register.

All four buffer register locations should be written to with correct data. If less than four words are being written to in the block of four words, then a read from the program memory location(s) not being written to must be performed. This takes the data from the program memory location(s) not being written and loads it into the PMDATL and PMDATH registers. Then the sequence of events to transfer data to the buffer registers must be executed.

To transfer data from the buffer registers to the program memory, the PMADRL and PMADRH registers must point to the last location in the four-word block (PMADRL<1:0> = 11). Then the following sequence of events must be executed:

1. Write 55h, then AAh, to PMCON2 (Flash programming sequence).
2. Set the WR control bit in the PMCON1 register to begin the write operation.

The user must follow the same specific sequence to initiate the write for each word in the program block, writing each program word in sequence (000, 001, 010, 011). When the write is performed on the last word (PMADRL<1:0> = 11), a block of sixteen words is automatically erased and the content of the four-word buffer registers are written into the program memory.

After the “BSF PMCON1, WR” instruction, the processor requires two cycles to set up the erase/write operation. The user must place two NOP instructions after the WR bit is set. Since data is being written to buffer registers, the writing of the first three words of the block appears to occur immediately. The processor will halt internal operations for the typical 4 ms, only during the cycle in which the erase takes place (i.e., the last word of the sixteen-word block erase). This is not Sleep mode, as the clocks and peripherals will continue to run. After the four-word write cycle, the processor will resume operation with the third instruction after the PMCON1 write instruction. The above sequence must be repeated for the higher 12 words.

**Note:** An erase is only initiated for the write of four words, just after a row boundary; or PMCON1<WR> set with PMADRL<3:0> = xxxx0011.

Refer to Figure 18-2 for a block diagram of the buffer registers and the control signals for test mode.

18.3.3 PROTECTION AGAINST SPURIOUS WRITE

There are conditions when the device should not write to the program memory. To protect against spurious writes, various mechanisms have been built in. On power-up, WREN is cleared. Also, the Power-Up Timer (72 ms duration) prevents program memory writes.

The write initiate sequence and the WREN bit help prevent an accidental write during a power glitch or software malfunction.

18.3.4 OPERATION DURING CODE PROTECT

When the device is code-protected, the CPU is able to read and write unscrambled data to the program memory. The test mode access is disabled.

18.3.5 OPERATION DURING WRITE PROTECT

When the program memory is write-protected, the CPU can read and execute from the program memory. The portions of program memory that are write-protected cannot be modified by the CPU using the PMCON registers. The write protection has no effect in ICSP mode.
**FIGURE 18-2: BLOCK WRITES TO 4K FLASH PROGRAM MEMORY**

If at new row sixteen words of Flash are erased, then four buffers are transferred to Flash automatically after this word is written.

**FIGURE 18-3: FLASH PROGRAM MEMORY LONG WRITE CYCLE EXECUTION**
19.0 I/O PORTS

In general, when a peripheral is enabled, that pin may not be used as a general purpose I/O pin.

Each port has two registers for its operation. These registers are:
- TRISGPx registers (data direction register)
- PORTGPx registers (read the levels on the pins of the device)

Some ports may have one or more of the following additional registers. These registers are:
- ANSELx (analog select)
- WPUx (weak pull-up)

Ports with analog functions also have an ANSELx register, which can disable the digital input and save power. A simplified model of a generic I/O port, without the interfaces to other peripherals, is shown in Figure 19-1.

FIGURE 19-1: GENERIC I/O PORTGPX OPERATION

19.1 Alternate Pin Function

The Alternate Pin Function Control (APFCON) register is used to steer specific peripheral input and output functions between different pins. The APFCON register is shown in Register 19-1. For the MCP19119 device, the following function can be moved between different pins:

- Frequency Synchronization Clock Input/Output

This bit has no effect on the values of any TRIS register. PORT and TRIS overrides will be routed to the correct pin. The unselected pin will be unaffected.

19.2 PORTGPA and TRISGPA Registers

PORTGPA is an 8-bit wide, bidirectional port consisting of five CMOS I/O, two open-drain I/O and one open-drain input-only pin. The corresponding data direction register is TRISGPA (Register 19-3). Setting a TRISGPA bit (= 1) will make the corresponding PORTGPA pin an input (i.e., disable the output driver). Clearing a TRISGPA bit (= 0) will make the corresponding PORTGPA pin an output (i.e., enables output driver). The exception is GPA5, which is input only and its TRISGPA bit will always read as ‘1’.

Example 19-1 shows how to initialize an I/O port.

Reading the PORTGPA register (Register 19-2) reads the status of the pins, whereas writing to it will write to the PORT latch. All write operations are read-modify-write operations.

The TRISGPA register (Register 19-3) controls the PORTGPA pin output drivers, even when they are being used as analog inputs. The user must ensure the bits in the TRISGPA register are maintained set when using them as analog inputs. I/O pins configured as analog input always read ‘0’. If the pin is configured for a digital output (either port or alternate function), the TRISGPA bit must be cleared in order for the pin to drive the signal and a read will reflect the state of the pin.

19.2.1 INTERRUPT-ON-CHANGE

Each PORTGPA pin is individually configurable as an interrupt-on-change pin. Control bits IOCA<7:0> enable or disable the interrupt function for each pin. The interrupt-on-change feature is disabled on a Power-On Reset. Refer to Section 20.0 “Interrupt-on-Change” for more information.

19.2.2 WEAK PULL-UPS

PORTGPA <3:0> and PORTGPA5 have an internal weak pull-up. PORTGPA<7:6> are special ports for the SSP module and do not have weak pull-ups. Individual control bits can enable or disable the internal weak pull-ups (see Register 19-4). The weak pull-up is automatically turned off when the port pin is configured as an output, an alternative function or on a Power-On Reset setting the RAPU bit in the OPTION_REG register. The weak pull-up on GPA5 is enabled when configured as MCLR pin by setting bit 5 in the Configuration Word register and disabled when GPA5 is an I/O. There is no software control of the MCLR pull-up.
19.2.3 ANSELA REGISTER

The ANSELA register (Register 19-5) is used to configure the Input mode of an I/O pin to analog. Setting the appropriate ANSELA bit high will cause all digital reads on the pin to be read as '0' and allows analog functions on the pin to operate correctly.

The state of the ANSELA bits has no effect on the digital output functions. A pin with TRISGPA clear and ANSELA set will still operate as a digital output, but the Input mode will be analog. This can cause unexpected behavior when executing read-modify-write instructions on the affected port.

**Note:** The ANSELA bits default to the Analog mode after Reset. To use any pins as digital general purpose or peripheral inputs, the corresponding ANSELA bits must be initialized to '0' by user software.

19.2.4 PORTGPA FUNCTIONS AND OUTPUT PRIORITIES

Each PORTGPA pin is multiplexed with other functions. The pins, their combined functions and their output priorities are shown in Table 19-1. For additional information, refer to the appropriate section in this data sheet.

PORTGPA pins GPA7 and GPA4 are true open-drain pins with no connection back to VDD.

When multiple outputs are enabled, the actual pin control goes to the peripheral with the highest priority.

Analog input functions, such as ADC, are not shown in the priority lists. These inputs are active when the I/O pin is set for Analog mode using the ANSELA register. Digital output functions may control the pin when it is in Analog mode with the priority shown in Table 19-1.

Legend: — = unimplemented locations read as ‘0’. Shaded cells are not used by PORTGPA.
19.3 PORTGPB and TRISGPB Registers

PORTGPB is an 8-bit wide, bidirectional port consisting of seven general purpose I/O ports. The corresponding data direction register is TRISGPB (Register 19-7). Setting a TRISGPB bit (= 1) will make the corresponding PORTGPB pin an input (i.e., disable the output driver). Clearing a TRISGPB bit (= 0) will make the corresponding PORTGPB pin an output (i.e., enable the output driver). Example 19-1 shows how to initialize an I/O port.

Some pins for PORTGPB are multiplexed with an alternate function for the peripheral or a clock function. In general, when a peripheral or clock function is enabled, that pin may not be used as a general purpose I/O pin.

Reading the PORTGPB register (Register 19-6) reads the status of the pins, whereas writing to it will write to the PORT latch. All write operations are read-modify-write operations.

The TRISGPB register (Register 19-7) controls the PORTGPB pin output drivers, even when they are being used as analog inputs. The user should ensure the bits in the TRISGPB register are maintained set when using them as analog inputs. I/O pins configured as analog input always read ‘0’. If the pin is configured for a digital output (either port or alternate function), the TRISGPB bit must be cleared in order for the pin to drive the signal and a read will reflect the state of the pin.

19.3.1 INTERRUPT-ON-CHANGE

Each PORTGPB pin is individually configurable as an interrupt-on-change pin. Control bits IOCB<7:4> and IOCB<2:0> enable or disable the interrupt function for each pin. The interrupt-on-change feature is disabled on a Power-On Reset. Refer to Section 20.0 “Interrupt-on-Change” for more information.

19.3.2 WEAK PULL-UPS

Each of the PORTGPB pins has an individually configurable internal weak pull-up. Control bits WPUB<7:4> and WPUB<2:1> enable or disable each pull-up (see Register 19-8). Each weak pull-up is automatically turned off when the port pin is configured as an output. All pull-ups are disabled on a Power-On Reset by the RAPU bit in the OPTION_REG register.

19.3.3 ANSELB REGISTER

The ANSELB register (Register 19-9) is used to configure the Input mode of an I/O pin to analog. Setting the appropriate ANSELB bit high will cause all digital reads on the pin to be read as ‘0’ and allows analog functions on the pin to operate correctly.

Note: The ANSELB bits default to the Analog mode after Reset. To use any pins as digital general purpose or peripheral inputs, the corresponding ANSELB bits must be initialized to ‘0’ by the user’s software.

19.3.4 PORTGPB FUNCTIONS AND OUTPUT PRIORITIES

Each PORTGPB pin is multiplexed with other functions. The pins, their combined functions and their output priorities are shown in Table 19-3. For additional information, refer to the appropriate section in this data sheet.

PORTGPB pin GPB0 is a true open-drain pin with no connection back to VDD.

When multiple outputs are enabled, the actual pin control goes to the peripheral with the highest priority.

Analog input functions, such as ADC, and some digital input functions are not included in the list below. These inputs are active when the I/O pin is set for Analog mode using the ANSELB registers. Digital output functions may control the pin when it is in Analog mode, with the priority shown in Table 19-3.

TABLE 19-3: PORTGPB OUTPUT PRIORITY

<table>

**Legend:** — = unimplemented locations read as ‘0’. Shaded cells are not used by PORTGPB.
INTERRUPT-ON-CHANGE

Each PORTGPA and PORTGPB pin is individually configurable as an interrupt-on-change pin. Control bits IOCA and IOCB enable or disable the interrupt function for each pin. Refer to Registers 20-1 and 20-2. The interrupt-on-change is disabled on a Power-On Reset.

The interrupt-on-change on GPA5 is disabled when configured as MCLR pin in the Configuration Word register.

For enabled interrupt-on-change pins, the values are compared with the old value latched on the last read of PORTGPA or PORTGPB. The mismatched outputs of the last read of all the PORTGPA and PORTGPB pins are OR’ed together to set the Interrupt-on-Change Interrupt Flag bit (IOCF) in the INTCON register.

Enabling the Module

To allow individual port pins to generate an interrupt, the IOCIE bit in the INTCON register must be set. If the IOCIE bit is disabled, the edge detection on the pin will still occur, but an interrupt will not be generated.

Individual Pin Configuration

To enable a pin to detect an interrupt-on-change, the associated IOCAx or IOCBx bit in the IOCA or IOCB register is set.

Clearing Interrupt Flags

The user, in the Interrupt Service Routine, clears the interrupt by:

a) Any read of PORTGPA or PORTGPB AND Clear flag bit IOCF. This will end the mismatch condition;

OR

b) Any write of PORTGPA or PORTGPB AND Clear flag bit IOCF will end the mismatch condition.

A mismatch condition will continue to set flag bit IOCF. Reading PORTGPA or PORTGPB will end the mismatch condition and allow flag bit IOCF to be cleared. The latch holding the last read value is not affected by a MCLR Reset. After this Reset, the IOCF flag will continue to be set if a mismatch is present.

Note: If a change on the I/O pin should occur when any PORTGPA or PORTGPB operation is being executed, then the IOCF interrupt flag may not get set.

Operation in Sleep

The interrupt-on-change interrupt sequence will wake the device from Sleep mode, if the IOCE bit is set.

21.0 INTERNAL TEMPERATURE INDICATOR MODULE

The MCP19118/19 is equipped with a temperature circuit designed to measure the operating temperature of the silicon die. The circuit's operating temperature range is -40°C to +125°C. The output is a voltage that is proportional to the device temperature. The output of the temperature indicator is internally connected to the device ADC.

21.1 Circuit Operation

The TMPSEN bit in the ABECON register (Register 6-15) is set to enable the internal temperature measurement circuit. The MCP19118/19 overtemperature shutdown feature is NOT controlled by this bit.

21.2 Temperature Output

The output of the circuit is measured using the internal analog-to-digital converter. Channel 10 is reserved for the temperature circuit output. Refer to Section 22.0 “Analog-to-Digital Converter (ADC) Module” for detailed information.

The temperature of the silicon die can be calculated by the ADC measurement using Equation 21-1.

\[
\text{EQUATION 21-1: SILICON DIE TEMPERATURE} \\
\text{TEMP}_\text{DIE} = \frac{\text{ADC READING} - 1.75}{13.3mV/\degree C}
\]
22.0 ANALOG-TO-DIGITAL CONVERTER (ADC) MODULE

The Analog-to-Digital Converter (ADC) allows conversion of an analog input signal to a 10-bit binary representation of that signal. This device uses analog inputs, which are multiplexed into a single sample and hold circuit. The output of the sample and hold is connected to the input of the converter. The converter generates a 10-bit binary result via successive approximation and stores the right justified conversion result into the ADC result registers (ADRESH:ADRESL register pair). Figure 22-1 shows the block diagram of the ADC.

The internal band gap supplies the voltage reference to the ADC.

The ADC can generate an interrupt upon completion of a conversion. This interrupt can be used to wake-up the device from Sleep.

FIGURE 22-1: ADC BLOCK DIAGRAM

Note 1: When ADON = 0, all multiplexer inputs are disconnected.

2: See the ADCON0 register (Register 22-1) for detailed analog channel selection per device.

3: Not implemented on MCP19118.
22.1 ADC Configuration

When configuring and using the ADC, the following functions must be considered:

- Port configuration
- Channel selection
- ADC conversion clock source
- Interrupt control
- Result formatting

22.1.1 PORT CONFIGURATION

The ADC can be used to convert both analog and digital signals. When converting analog signals, the I/O pin should be configured for analog by setting the associated TRIS and ANSEL bits. Refer to Section 19.0 “I/O Ports” for more information.

Note: Analog voltages on any pin that is defined as a digital input may cause the input buffer to conduct excess current.

22.1.2 CHANNEL SELECTION

There are up to 19 channel selections available on the MCP19118 and 21 channel selections available on the MCP19119:

- AN<6:0> pins
- VIN_ANA: 1/13 of the input voltage (V_IN)
- VREGREF: VOUT reference voltage
- OV_REF: reference for OV comparator
- UV_REF: reference for UV comparator
- VBGR: band gap reference
- VOUT: output voltage
- CRT: voltage proportional to the AC inductor current
- VZC: an internal ground, Voltage for Zero Current
- DEMAND: input to slope compensation circuitry
- RELEFF: relative efficient measurement channel
- TMP_ANA: voltage proportional to silicon die temperature
- ANA_IN: for a multi-phase slave, error amplifier signal received from master
- DCI: DC inductor valley current

The CHS<4:0> bits in the ADCON0 register determine which channel is connected to the sample and hold circuit.

When changing channels, a delay is required before starting the next conversion. Refer to Section 22.2 “ADC Operation” for more information.

22.1.3 ADC CONVERSION CLOCK

The source of the conversion clock is software-selectable via the ADON1<ADCS> bits. There are five possible clock options:

- FOSC/8
- FOSC/16
- FOSC/32
- FOSC/64
- FRC (clock derived from internal oscillator with a divisor of 16)

The time to complete one bit conversion is defined as T_AD. One full 10-bit conversion requires 11 T_AD periods, as shown in Figure 22-2.

For a correct conversion, the appropriate T_AD specification must be met. Refer to the A/D conversion requirements in Section 5.0 “Digital Electrical Characteristics” for more information. Table 22-1 gives examples of appropriate ADC clock selections.

Note: Unless using the FRC, any changes in the system clock frequency will change the ADC clock frequency, which may adversely affect the ADC result.

### TABLE 22-1: ADC CLOCK PERIOD (T AD) VS. DEVICE OPERATING FREQUENCIES

<table>
<thead>
<tr>
<th>ADC Clock Source</th>
<th>ADCS&lt;2:0&gt;</th>
<th>8 MHz</th>
</tr>
</thead>
<tbody>
<tr>
<td>FOSC/8</td>
<td>0 0 1</td>
<td>1.0 µs (2)</td>
</tr>
<tr>
<td>FOSC/16</td>
<td>0 1 0</td>
<td>2.0 µs</td>
</tr>
<tr>
<td>FOSC/32</td>
<td>0 1 0</td>
<td>4.0 µs</td>

<td>1 1 0</td>
<td>8.0 µs (3)</td>
</tr>
<tr>
<td>FRC</td>
<td>x 1 1</td>
<td>2.0-6.0 µs (1, 4)</td>
</tr>
</tbody>
</table>

Legend: Shaded cells are outside of recommended range.

Note 1: The FRC source has a typical T_AD time of 4 µs for VDD > 3.0V.

2: These values violate the minimum required T_AD time.

3: For faster conversion times, the selection of another clock source is recommended.

4: The FRC clock source is only recommended if the conversion will be performed during Sleep.
22.1.4  INTERRUPTS

The ADC module allows for the ability to generate an interrupt upon completion of an Analog-to-Digital conversion. The ADC Interrupt Flag is the PIR1<ADIF> bit. The ADC Interrupt Enable is the PIE1<ADIE> bit. The ADIF bit must be cleared in software.

Note 1: The ADIF bit is set at the completion of every conversion, regardless of whether or not the ADC interrupt is enabled.

2: The ADC operates during Sleep only when the FRC oscillator is selected.

This interrupt can be generated while the device is operating or while in Sleep. If the device is in Sleep, the interrupt will wake-up the device. Upon waking from Sleep, the next instruction following the SLEEP instruction is always executed. If the user is attempting to wake-up from Sleep and resume in-line code execution, the INTCON<GIE> and INTCON<PEIE> bits must be disabled. If the INTCON<GIE> and INTCON<PEIE> bits are enabled, execution will switch to the Interrupt Service Routine.

22.1.5  RESULT FORMATTING

The 10-bit A/D conversion result is supplied in right justified format only. Figure 22-3 shows the output format.
22.2 ADC Operation

22.2.1 STARTING A CONVERSION
To enable the ADC module, the ADCON0<ADON> bit must be set to a ‘1’. Setting the ADCON0<GO/DONE> bit to a ‘1’ will start the Analog-to-Digital conversion.

22.2.2 COMPLETION OF A CONVERSION
When the conversion is complete, the ADC module will:
• Clear the GO/DONE bit
• Set the ADIF Interrupt Flag bit
• Update the ADRESH:ADRESL registers with new conversion result

22.2.3 TERMINATING A CONVERSION
If a conversion must be terminated before completion, the GO/DONE bit can be cleared in software. The ADRESH:ADRESL registers will not be updated with the partially complete Analog-to-Digital conversion sample. Instead, the ADRESH:ADRESL register pair will retain the value of the previous conversion. Additionally, a two TAD delay is required before another acquisition can be initiated. Following the delay, an input acquisition is automatically started on the selected channel.

22.2.4 ADC OPERATION DURING SLEEP
The ADC module can operate during Sleep. This requires the ADC clock source to be set to the FRC option. When the FRC clock source is selected, the ADC waits one additional instruction before starting the conversion. This allows the SLEEP instruction to be executed, which can reduce system noise during the conversion. If the ADC interrupt is enabled, the device will wake-up from Sleep when the conversion completes. If the ADC interrupt is disabled, the ADC module is turned off after the conversion completes, although the ADON bit remains set.

When the ADC clock source is something other than FRC, a SLEEP instruction causes the present conversion to be aborted and the ADC module is turned off, although the ADON bit remains set.

22.2.5 A/D CONVERSION PROCEDURE
This is an example procedure for using the ADC to perform an Analog-to-Digital conversion:

1. Configure Port:
   • Disable pin output driver (Refer to the TRIS register)
   • Configure pin as analog (Refer to the ANSEL register)

2. Configure the ADC module:
   • Select ADC conversion clock
   • Select ADC input channel
   • Turn on ADC module

3. Configure ADC interrupt (optional):
   • Clear ADC interrupt flag
   • Enable ADC interrupt
   • Enable peripheral interrupt
   • Enable global interrupt

4. Wait the required acquisition time.
5. Start conversion by setting the GO/DONE bit.
6. Wait for ADC conversion to complete by one of the following:
   • Polling the GO/DONE bit
   • Waiting for the ADC interrupt (interrupts enabled)
7. Read ADC Result.
8. Clear the ADC interrupt flag (required if interrupt is enabled).

EXAMPLE 22-1: A/D CONVERSION

```
;This code block configures the ADC.
;for polling, Frc clock and AN0 input.

;Conversion start & polling for completion are included.

BANKSEL ADCON1
MOVFW B‘01110000’;Frc clock
MOVWF ADCON1

BANKSEL TRISGA
BSF TRISGA,0;Set GPA0 to input

BANKSEL ANSELA
BSF ANSELA,0;Set GPA0 to analog

BANKSEL ADCON0

MOVLW B‘01000001’;Select channel AN0
MOVWF ADCON0;Turn ADC On

CALL SampleTime;Acquisition delay

BSF ADCON0,1;Start conversion

BTFSC ADCON0,1;Is conversion done?
GOTO $-1;No, test again

BANKSEL ADRESH
MOVWF ADRESH,W;Read upper 2 bits

MOVWF RESULTHI;store in GPR space

BANKSEL ADRESL

MOVWF ADRESL,W;Read lower 8 bits

MOVWF RESULTLO;Store in GPR space
```

Note: The GO/DONE bit should not be set in the same instruction that turns on the ADC. Refer to Section 22.2.5 “A/D Conversion Procedure”.

Note: A device Reset forces all registers to their Reset state. Thus, the ADC module is turned off and any pending conversion is terminated.

Note 1: The global interrupt can be disabled if the user is attempting to wake-up from Sleep and resume in-line code execution.
2: Refer to Section 22.4 “A/D Acquisition Requirements”.

22.4 A/D Acquisition Requirements

For the ADC to meet its specified accuracy, the charge holding capacitor (C_HOLD) must be allowed to fully charge to the input channel voltage level. The Analog Input model is shown in Figure 22-4. The source impedance (R_S) and the internal sampling switch (R_SS) impedance directly affect the time required to charge the capacitor C_HOLD. The sampling switch (R_SS) impedance varies over the device voltage (V_DD); refer to Figure 22-4.

The maximum recommended impedance for analog sources is 10 kΩ. As the source impedance is decreased, the acquisition time may be decreased. After the analog input channel is selected (or changed), an A/D acquisition must be done before the conversion can be started. To calculate the minimum acquisition time, Equation 22-1 may be used. This equation assumes that 1/2 LSB error is used (1,024 steps for the ADC). The 1/2 LSB error is the maximum error allowed for the ADC to meet its specified resolution.

**EQUATION 22-1: ACQUISITION TIME EXAMPLE**

![Equation Image]

Assumptions: Temperature = +50°C and external impedance of 10 kΩ 5.0V V_DD

\[
T_{ACQ} = T_{AMP} + T_C + T_{COFF}
\]

The value for \( T_C \) can be approximated with the following equations:

\[
V_{APPLIED}\left(1 - \frac{1}{(2^n + 1)}\right) = V_{CHOLD}
\]

\( \text{[1] } V_{CHOLD} \text{ charged to within 1/2 lsb} \)

\[
V_{APPLIED}\left(1 - e^{-\frac{-T_C}{RC}}\right) = V_{CHOLD}
\]

\( \text{[2] } V_{CHOLD} \text{ charge response to } V_{APPLIED} \)

\[
V_{APPLIED}\left(1 - e^{-\frac{-T_C}{RC}}\right) = V_{APPLIED}\left(1 - \frac{1}{(2^n + 1)}\right)
\]

\( \text{combining [1] and [2]} \)

Note: Where \( n = \) number of bits of the ADC.

Solving for \( T_C \):

\[
T_C = -C_{HOLD}(R_{IC} + R_{SS} + R_S) \ln(1/2047)
\]

\[
= -10 \text{ pF}(1 \text{ kΩ} + 7 \text{ kΩ} + 10 \text{ kΩ}) \ln(0.0004885)
\]

\[
= 1.37 \mu s
\]

Therefore:

\[
T_{ACQ} = 2 \mu s + 1.37 \mu s + [(50°C - 25°C)(0.05 \mu s/°C)]
\]

\[
= 4.67 \mu s
\]

**Note 1:** The charge holding capacitor (C_HOLD) is not discharged after each conversion.

**Note 2:** The maximum recommended impedance for analog sources is 10 kΩ. This is required to meet the pin leakage specification.
FIGURE 22-4: ANALOG INPUT MODEL

Legend:
- \( C_{\text{HOLD}} \): Sample/ Hold Capacitance
- \( C_{\text{PIN}} \): Input Capacitance
- \( I_{\text{LEAKAGE}} \): Leakage current at the pin due to various junctions

23.0 TIMER0 MODULE

The Timer0 module is an 8-bit timer/counter with the following features:

• 8-bit timer/counter register (TMR0)
• 8-bit prescaler (independent of Watchdog Timer)
• Programmable internal or external clock source
• Programmable external clock edge selection
• Interrupt on overflow

Figure 23-1 is a block diagram of the Timer0 module.

FIGURE 23-1: BLOCK DIAGRAM OF TIMER0

23.1 Timer0 Operation

The Timer0 module can be used as either an 8-bit timer or an 8-bit counter.

23.1.1 8-BIT TIMER MODE

The Timer0 module will increment every instruction cycle, if used without a prescaler. 8-Bit Timer mode is selected by clearing the T0CS bit in the OPTION_REG register.

When TMR0 is written, the increment is inhibited for two instruction cycles immediately following the write.

8-Bit Counter mode using the T0CKI pin is selected by setting the OPTION_REG<T0CS> bit to '1'.

23.1.2 8-BIT COUNTER MODE

In 8-Bit Counter mode, the Timer0 module will increment on every rising or falling edge of the T0CKI pin. The incrementing edge is determined by the OPTION_REG<T0SE> bit.

8-Bit Counter mode using the T0CKI pin is selected by setting the OPTION_REG<T0CS> bit to ‘1’.

23.1.3 SOFTWARE-PROGRAMMABLE PRESCALER

A single software-programmable prescaler is available for use with either Timer0 or the Watchdog Timer (WDT), but not both simultaneously. The prescaler assignment is controlled by the OPTION_REG<PSA> bit. To assign the prescaler to Timer0, the PSA bit must be cleared to ‘0’.

There are eight prescaler options for the Timer0 module ranging from 1:2 to 1:256. The prescale values are selectable via the PS<2:0> bits in the OPTION_REG register. In order to have a 1:1 prescaler value for the Timer0 module, the prescaler must be disabled by setting the OPTION_REG<PSA> bit.

The prescaler is not readable or writable. When assigned to the Timer0 module, all instructions writing to the TMR0 register will clear the prescaler.
23.1.4 SWITCHING PRESCALER BETWEEN TIMER0 AND WDT MODULES

As a result of having the prescaler assigned to either Timer0 or the WDT, it is possible to generate an unintended device Reset when switching prescaler values. When changing the prescaler assignment from Timer0 to the WDT module, the instruction sequence shown in Example 23-1 must be executed.

**EXAMPLE 23-1: CHANGING PRESCALER (TIMER0 → WDT)**

```assembly
BANKSEL TMR0 ;
CLRWDT ;Clear WDT
CLRF TMR0 ;Clear TMR0 and ;prescaler
BANKSEL OPTION_REG ;
BSF OPTION_REG,PSA ;Select WDT
CLRWDT ;
;
MOVLW b'11111000' ;Mask prescaler
ANDWF OPTION_REG,W ;bits
IORLW b'00000101' ;Set WDT prescaler
MOVWF OPTION_REG ;to 1:32
```

When changing the prescaler assignment from the WDT to the Timer0 module, the following instruction sequence must be executed (see Example 23-2).

**EXAMPLE 23-2: CHANGING PRESCALER (WDT → TIMER0)**

```assembly
CLRWDT ;Clear WDT and ;prescaler
BANKSEL OPTION_REG ;
MOVLW b'11110000' ;Mask TMR0 select and
ANDWF OPTION_REG,W ;prescaler bits
IORLW b'00000011' ;Set prescale to 1:16
MOVWF OPTION_REG ;
```

Note: The Timer0 interrupt cannot wake the processor from Sleep since the timer is frozen during Sleep.

23.1.5 TIMER0 INTERRUPT

Timer0 will generate an interrupt when the TMR0 register overflows from FFh to 00h. The INTCON<T0IF> interrupt flag bit is set every time the TMR0 register overflows, regardless of whether or not the Timer0 interrupt is enabled. The T0IF bit can only be cleared in software. The Timer0 interrupt enable is the INTCON<T0IE> bit.

23.1.6 USING TIMER0 WITH AN EXTERNAL CLOCK

When Timer0 is in Counter mode, the synchronization of the T0CKI input and the Timer0 register is accomplished by sampling the prescaler output on the Q2 and Q4 cycles of the internal phase clocks. Therefore, the high and low periods of the external clock source must meet the timing requirements, as shown in Section 5.0 “Digital Electrical Characteristics”.

23.1.7 OPERATION DURING SLEEP

Timer0 cannot operate while the processor is in Sleep mode. The contents of the TMR0 register will remain unchanged while the processor is in Sleep mode.

24.0 TIMER1 MODULE WITH GATE CONTROL

The Timer1 module is a 16-bit timer with the following features:
- 16-bit timer register pair (TMR1H:TMR1L)
- Readable and Writable (both registers)
- Selectable internal clock source
- 2-bit prescaler
- Interrupt on overflow

Figure 24-1 is a block diagram of the Timer1 module.

24.1 Timer1 Operation

The Timer1 module is a 16-bit incrementing timer which is accessed through the TMR1H:TMR1L register pair. Writes to TMR1H or TMR1L directly update the counter. The timer is incremented on every instruction cycle.

Timer1 is enabled by configuring the T1CON<TMR1ON> bit. Table 24-1 displays the Timer1 enable selections.

24.2 Clock Source Selection

The T1CON<TMR1CS> bit is used to select the clock source for Timer1. Table 24-1 displays the clock source selections.

24.2.1 INTERNAL CLOCK SOURCE

The TMR1H:TMR1L register pair will increment on multiples of FOSC or FOSC/4 as determined by the Timer1 prescaler.

As an example, when the FOSC internal clock source is selected, the Timer1 register value will increment by four counts every instruction clock cycle.

**TABLE 24-1: CLOCK SOURCE SELECTIONS**

<td>2 MHz instruction clock (FOSC/4)</td>
</tr>
</tbody>
</table>
24.3 Timer1 Prescaler

Timer1 has four prescaler options allowing 1, 2, 4 or 8 divisions of the clock input. The TCON<T1CKPS> bits control the prescale counter. The prescale counter is not directly readable or writable; however, the prescaler counter is cleared upon a write to TMR1H or TMR1L.

24.4 Timer1 Interrupt

The Timer1 register pair (TMR1H:TMR1L) increments to FFFFh and rolls over to 0000h. When Timer1 rolls over, the Timer1 interrupt flag bit in the PIR1 register is set. To enable the interrupt on rollover, you must set these bits:
- TCON<TMR1ON> bit
- PIE1<TMR1IE> bit
- INTCON<PEIE> bit
- INTCON<GIE> bit

The interrupt is cleared by clearing the TMR1IF bit in the Interrupt Service Routine.

Note: The TMR1H:TMR1L register pair and the TMR1IF bit should be cleared before enabling interrupts.

24.5 Timer1 in Sleep

Unlike other standard mid-range Timer1 modules, the MCP19118/19 Timer1 module only clocks from an internal system clock and thus does not run during Sleep mode, nor can it be used to wake the device from this mode.

24.6 Timer1 Control Register

The Timer1 Control (T1CON) register is used to control Timer1 and select the various features of the Timer1 module.

25.0 TIMER2 MODULE
The Timer2 module is an 8-bit timer with the following features:
- 8-bit timer register (TMR2)
- 8-bit period register (PR2)
- Interrupt on TMR2 match with PR2
- Software-programmable prescaler (1:1, 1:4, 1:16)
See Figure 25-1 for a block diagram of Timer2.

25.1 Timer2 Operation
The clock input to the Timer2 module is the system clock (FOSC). The clock is fed into the Timer2 prescaler, which has prescaler options of 1:1, 1:4 or 1:16. The output of the prescaler is then used to increment the TMR2 register.

The values of TMR2 and PR2 are constantly compared to determine when they match. TMR2 will increment from 00h until it matches the value in PR2. When a match occurs, TMR2 is reset to 00h on the next increment cycle.

The match output of the Timer2/PR2 comparator is used to set the PIR1<TMR2IF>.

The TMR2 and PR2 registers are both fully readable and writable. On any Reset, the TMR2 register is set to 00h and the PR2 register is set to FFh.

Timer2 is turned on by setting the T2CON<TMR2ON> bit to a '1'. Timer2 is turned off by clearing the TMR2ON bit to a '0'.

The Timer2 prescaler is controlled by the T2CON<T2CKPS> bits. The prescaler counter is cleared when:
- A write to TMR2 occurs
- A write to T2CON occurs
- Any device Reset occurs (Power-On Reset, MCLR Reset, Watchdog Timer Reset or Brown-Out Reset)

Note: TMR2 is not cleared when T2CON is written.

26.0 PWM MODULE

The CCP module implemented on the MCP19118/19 is a modified version of the CCP module found in standard mid-range microcontrollers. In the MCP19118/19, the PWM module is used to generate the system clock or system oscillator. This system clock will control the MCP19118/19 switching frequency, as well as set the maximum allowable duty cycle. The PWM module does not continuously adjust the duty cycle to control the output voltage. This is accomplished by the analog control loop and associated circuitry.

26.1 Standard Pulse-Width Modulation (PWM) Mode

The PWM module output signal is used to set the operating switching frequency and maximum allowable duty cycle of the MCP19118/19. The actual duty cycle on the HDRV and LDRV is controlled by the analog PWM control loop. However, this duty cycle cannot be greater than the value in the PWMRL register.

There are two modes of operation that concern the system clock PWM signal. These modes are stand-alone (nonfrequency synchronization) and frequency synchronization.

26.1.1 STAND-ALONE (NONFREQUENCY SYNCHRONIZATION) MODE

When the MCP19118/19 is running stand-alone, the PWM signal functions as the system clock. It is operating at the programmed switching frequency with a programmed maximum duty cycle \((D_{CLOCK})\). The programmed maximum duty cycle is not adjusted on a cycle-by-cycle basis to control the MCP19118/19 system output. The required duty cycle \((D_{BUCK})\) to control the output is adjusted by the MCP19118/19 analog control loop and associated circuitry. \(D_{CLOCK}\) does, however, set the maximum allowable \(D_{BUCK}\).

\[
D_{BUCK} < 1 - D_{CLOCK}
\]

26.1.2 SWITCHING FREQUENCY SYNCHRONIZATION MODE

The MCP19118/19 can be programmed to be a switching frequency MASTER or SLAVE device. The MASTER device functions as described in Section 26.1.1 “Stand-Alone (NonFrequency Synchronization) Mode” with the exception of the system clock also being applied to GPA1.

A SLAVE device will receive the MASTER system clock on GPA1. This MASTER system clock will be OR’ed with the output of the TIMER2 module. This OR’ed signal will latch PWMRL into PWMRH and PWMPHL into PWMPHH.

Figure 26-1 shows a simplified block diagram of the CCP module in PWM mode.

The PWMPHL register allows for a phase shift to be added to the SLAVE system clock.

It is desired to have the MCP19118/19 SLAVE device’s system clock start point shifted by a programmed amount from the MASTER system clock. This SLAVE phase shift is specified by writing to the PWMPHL register. The SLAVE phase shift can be calculated by using the following equation.

\[
SLAVE\ phase\ shift = PWMPHL \cdot T_{OSC} \cdot (T2\ prescale\ value)
\]
A PWM output (Figure 26-2) has a time base (period) and a time that the output stays high (duty cycle). The frequency of the PWM is the inverse of the period (1/period).

**FIGURE 26-1: SIMPLIFIED PWM BLOCK DIAGRAM**

**EQUATION 26-3:**

\[
PWM\ Period = \left( \frac{(PR2) + 1}{T_{OSC} \times T2\ PreSCALE\ Value} \right)
\]

When TMR2 is equal to PR2, the following two events occur on the next increment cycle:

- TMR2 is cleared
- The PWM duty cycle is latched from PWMRL into PWMRH
26.1.4 PWM DUTY CYCLE (D\text{CLOCK})

The PWM duty cycle (D\text{CLOCK}) is specified by writing to the PWMRL register. Up to 8-bit resolution is available. The following equation is used to calculate the PWM duty cycle (D\text{CLOCK}):

EQUATION 26-4:

\[ \text{PWM DUTY CYCLE} = \text{PWMRL} \times T_{\text{OSC}} \times (T2 \text{ PRESCALE VALUE}) \]

The PWMRL bits can be written to at any time, but the duty cycle value is not latched into PWMRH until after a match between PR2 and TMR2 occurs.

26.2 Operation during Sleep

When the device is placed in Sleep, the allocated timer will not increment and the state of the module will not change. If the CLKPIN pin is driving a value, it will continue to drive that value. When the device wakes up, it will continue from this state.

27.0  MASTER SYNCHRONOUS SERIAL PORT (MSSP) MODULE

27.1  Master SSP (MSSP) Module

Overview

The Master Synchronous Serial Port (MSSP) module is a serial interface useful for communicating with other peripheral or microcontroller devices. These peripheral devices may be Serial EEPROMs, shift registers, display drivers, A/D converters, etc. The MSSP module only operates in Inter-Integrated Circuit (I2C) mode.

The I2C interface supports the following modes and features:

- Master mode
- Slave mode
- Byte NACKing (Slave mode)
- Limited Multi-Master support
- 7-bit and 10-bit addressing
- Start and Stop interrupts
- Interrupt masking
- Clock stretching
- Bus collision detection
- General call address matching
- Dual Address masking
- Address Hold and Data Hold modes
- Selectable SDA hold times

Figure 27-1 is a block diagram of the I2C interface module in Master mode. Figure 27-2 is a diagram of the I2C interface module in Slave mode.
27.2 I²C MODE OVERVIEW

The Inter-Integrated Circuit Bus (I²C) is a multi-master serial data communication bus. Devices communicate in a master/slave environment, where the master devices initiate the communication. A slave device is controlled through addressing.

The MSSP module has eight registers for I²C operation. They are the:

- MSSP Status Register (SSPSTAT)
- MSSP Control Register1 (SSPCON1)
- MSSP Control Register2 (SSPCON2)
- MSSP Control Register3 (SSPCON3)
- Serial Receive/Transmit Buffer (SSPBUF)
- MSSP Shift Register (SSPSR) – Not directly accessible
- MSSP Address Register (SSPADD)
- MSSP Address Register2 (SSPADD2)
- MSSP Address Mask Register1 (SSPMSK)
- MSSP Address Mask Register2 (SSPMSK2)

The SSPCON1 register is used to define the I²C mode. Four selection bits (SSPCON1<3:0>) allow one of the following I²C modes to be selected:

- I²C Slave mode (7-bit address)
- I²C Slave mode (10-bit address)
- I²C Master mode, clock = OSC/4 (SSPADD +1)
- I²C firmware controlled Master mode (Slave idle)

The SSPSTAT register gives the status of the data transfer. This information includes detection of a START or STOP bit, specifies if the data received byte was data or address, if the next byte is completion of the 10-bit address and if this will be a read or write data transfer.

The SSPBUF is the register to which transfer data is written to or read from. The SSPSR register shifts the data in or out of the device. In receive operation, the SSPBUF and SSPSR create a double buffer receiver. This allows reception of the next byte to begin before reading the last byte of received data. When the complete byte is received before the SSPBUF register is read, a receiver overflow has occurred, the SSPOV bit (SSPCON1<6>) is set and the byte in the SSPSR is lost.
The I2C bus specifies two signal connections:

• Serial Clock (SCL)
• Serial Data (SDA)

Both the SCL and SDA connections are bidirectional open-drain lines, each requiring pull-up resistors for the supply voltage. Pulling the line to ground is considered a logical zero; letting the line float is considered a logical one.

Before selecting any I2C mode, the SCL and SDA pins must be programmed to inputs by setting the appropriate TRIS bits. Selecting I2C mode, by setting the SSPEN bit, enables the SCL and SDA pins to be used as clock and data lines in I2C mode.

Figure 27-3 shows a typical connection between two devices configured as master and slave.

![FIGURE 27-3: I2C MASTER/SLAVE CONNECTION](image)

The I2C bus can operate with one or more master devices and one or more slave devices.

There are four potential modes of operation for a given device:

• Master Transmit mode (master is transmitting data to a slave)
• Master Receive mode (master is receiving data from a slave)
• Slave Transmit mode (slave is transmitting data to a master)
• Slave Receive mode (slave is receiving data from the master)

To begin communication, a master device starts out in Master Transmit mode. The master device sends out a Start bit followed by the address byte of the slave it intends to communicate with. This is followed by a single Read/Write bit, which determines whether the master intends to transmit to or receive data from the slave device.

If the requested slave exists on the bus, it will respond with an Acknowledge bit, otherwise known as an ACK. The master then continues in either Transmit mode or Receive mode and the slave continues in the complement, either in Receive mode or Transmit mode, respectively.

A Start bit is indicated by a high-to-low transition of the SDA line while the SCL line is held high. Address and data bytes are sent out. Most Significant bit (MSb) first. The Read/Write bit is sent out as a logical one when the master intends to read data from the slave and is sent out as a logical zero when it intends to write data to the slave.

The Acknowledge (ACK) bit is an active-low signal, which holds the SDA line low to indicate to the transmitter that the slave device has received the transmitted data and is ready to receive more.

The transition of a data bit is always performed while the SCL line is held low. Transitions that occur while the SCL line is held high are used to indicate Start and Stop bits.

If the master intends to write to the slave, then it repeatedly sends out a byte of data, with the slave responding after each byte with an ACK bit. In this example, the master device is in Master Transmit mode and the slave is in Slave Transmit mode.

If the master intends to read from the slave, then it repeatedly receives a byte of data from the slave and responds after each byte with an ACK bit. In this example, the master device is in Master Receive mode and the slave is Slave Transmit mode.

On the last byte of data communicated, the master device may end the transmission by sending a Stop bit. If the master device is in Receive mode, it sends the Stop bit in place of the last ACK bit. A Stop bit is indicated by a low-to-high transition of the SDA line, while the SCL line is held high.

In some cases, the master may want to maintain control of the bus and reinitiate another transmission. If so, the master device may send another Start bit in place of the Stop bit or last ACK bit when it is in Receive mode.

The I2C bus specifies three message protocols:

• Single message where a master writes data to a slave
• Single message where a master reads data from a slave
• Combined message where a master initiates a minimum of two writes, or two reads, or a combination of writes and reads, to one or more slaves

When one device is transmitting a logical one or letting the line float and a second device is transmitting a logical zero or holding the line low, the first device can detect that the line is not a logical one. This detection, when used on the SCL line, is called clock stretching. Clock stretching gives slave devices a mechanism to control the flow of data. When this detection is used on the SDA line, it is called arbitration. Arbitration ensures that there is only one master device communicating at any single time.
27.2.1 CLOCK STRETCHING
When a slave device has not completed processing data, it can delay the transfer of more data through the process of Clock Stretching. An addressed slave device may hold the SCL clock line low after receiving or sending a bit, indicating that it is not yet ready to continue. The master that is communicating with the slave will attempt to raise the SCL line in order to transfer the next bit, but will detect that the clock line has not yet been released. Because the SCL connection is open-drain, the slave has the ability to hold that line low until it is ready to continue communicating.

Clock stretching allows receivers that cannot keep up with a transmitter to control the flow of incoming data.

27.2.2 ARBITRATION
Each master device must monitor the bus for Start and Stop bits. If the device detects that the bus is busy, it cannot begin a new message until the bus returns to an Idle state.

However, two master devices may try to initiate a transmission on or about the same time. When this occurs, the process of arbitration begins. Each transmitter checks the level of the SDA data line and compares it to the level that it expects to find. The first transmitter to observe that the two levels don't match loses arbitration and must stop transmitting on the SDA line.

For example, if one transmitter holds the SDA line to a logical one (lets it float) and a second transmitter holds it to a logical zero (pulls it low), the result is that the SDA line will be low. The first transmitter then observes that the level of the line is different than expected and concludes that another transmitter is communicating.

The first transmitter to notice this difference is the one that loses arbitration and must stop driving the SDA line. If this transmitter is also a master device, it also must stop driving the SCL line. It then can monitor the lines for a Stop condition before trying to reissue its transmission. In the meantime, the other device that has not noticed any difference between the expected and actual levels on the SDA line continues with its original transmission. It can do so without any complications, because so far, the transmission appears exactly as expected with no other transmitter disturbing the message.

Slave Transmit mode can also be arbitrated, when a master addresses multiple slaves, but this is less common.

If two master devices are sending a message to two different slave devices at the address stage, the master sending the lower slave address always wins arbitration. When two master devices send messages to the same slave address and addresses can sometimes refer to multiple slaves, the arbitration process must continue into the data stage.

Arbitration usually occurs very rarely, but it is a necessary process for proper multi-master support.

27.3 I²C MODE OPERATION
All MSSP I²C communication is byte-oriented and shifted out MSb first. Six SFR registers and two interrupt flags interface the module with the PIC microcontroller and user software. Two pins, SDA and SCL, are exercised by the module to communicate with other external I²C devices.

27.3.1 BYTE FORMAT
All communication in I²C is done in 9-bit segments. A byte is sent from a master to a slave or vice-versa, followed by an Acknowledge bit sent back. After the 8th falling edge of the SCL line, the device outputting data on the SDA changes that pin to an input and reads in an acknowledge value on the next clock pulse.

The clock signal, SCL, is provided by the master. Data is valid to change while the SCL signal is low and sampled on the rising edge of the clock. Changes on the SDA line while the SCL line is high define special conditions on the bus, explained below.

27.3.2 DEFINITION OF I²C TERMINOLOGY
There is language and terminology in the description of I²C communication that have definitions specific to I²C. That word usage is defined below and may be used in the rest of this document without explanation. This table was adapted from the Philips I²C specification.

27.3.3 SDA AND SCL PINS
On the MCP19118/19, the SCL and SDA pins are always open-drain. These pins should be set by the user to inputs by setting the appropriate TRIS bits.

Note: Data is tied to output zero when an I²C mode is enabled.
27.3.4 SDA HOLD TIME
The hold time of the SDA pin is selected by the SSP-CON3<SDAHT> bit. Hold time is the time SDA is held valid after the falling edge of SCL. Setting the SDAHT bit selects a longer 300 ns minimum hold time and may help on buses with large capacitance.

TABLE 27-1: I²C BUS TERMS

<table>
<thead>
<tr>
<th>TERM</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Transmitter</td>
<td>The device which shifts data out onto the bus.</td>
</tr>
<tr>
<td>Receiver</td>
<td>The device which shifts data in from the bus.</td>
</tr>
<tr>
<td>Master</td>
<td>The device that initiates a transfer, generates clock signals and terminates a transfer.</td>
</tr>
<tr>
<td>Slave</td>
<td>The device addressed by the master.</td>
</tr>
<tr>
<td>Multi-Master</td>
<td>A bus with more than one device that can initiate data transfers.</td>
</tr>
<tr>
<td>Arbitration</td>
<td>Procedure to ensure that only one master at a time controls the bus. Winning arbitration ensures that the message is not corrupted.</td>
</tr>
<tr>
<td>Synchronization</td>
<td>Procedure to synchronize the clocks of two or more devices on the bus.</td>
</tr>
<tr>
<td>Idle</td>
<td>No master is controlling the bus and both SDA and SCL lines are high.</td>
</tr>
<tr>
<td>Active</td>
<td>Any time one or more master devices are controlling the bus.</td>
</tr>
<tr>
<td>Addressed Slave</td>
<td>Slave device that has received a matching address and is actively being clocked by a master.</td>
</tr>
<tr>
<td>Matching Address</td>
<td>Address byte that is clocked into a slave that matches the value stored in SSPADDx.</td>
</tr>
<tr>
<td>Write Request</td>
<td>Slave receives a matching address with R/W bit clear and is ready to clock in data.</td>
</tr>
<tr>
<td>Read Request</td>
<td>Master sends an address byte with the R/W bit set, indicating that it wishes to clock data out of the slave. This data is the next and all following bytes until a Restart or Stop.</td>
</tr>
<tr>
<td>Clock Stretching</td>
<td>When a device on the bus holds SCL low to stall communication.</td>
</tr>
<tr>
<td>Bus Collision</td>
<td>Any time the SDA line is sampled low by the module while it is outputting and expected high state.</td>
</tr>
</tbody>
</table>

27.3.5 START CONDITION
The I²C specification defines a Start condition as a transition of SDA from a high to a low state, while SCL line is high. A Start condition is always generated by the master and signifies the transition of the bus from an Idle to an Active state. Figure 27-4 shows the wave forms for Start and Stop conditions.

A bus collision can occur on a Start condition if the module samples the SDA line low before asserting it low. This does not conform to the I²C Specification that states no bus collision can occur on a Start.

27.3.6 STOP CONDITION
A Stop condition is a transition of the SDA line from a low state to a high state while the SCL line is high.

Note: At least one SCL low time must appear before a Stop is valid. Therefore, if the SDA line goes low then high again while the SCL line stays high, only the Start condition is detected.

27.3.7 RESTART CONDITION
A Restart is valid any time that a Stop would be valid. A master can issue a Restart if it wishes to hold the bus after terminating the current transfer. A Restart has the same effect on the slave that a Start would, resetting all slave logic and preparing it to clock in an address. The master may want to address the same or another slave.

In 10-bit Addressing Slave mode, a Restart is required for the master to clock data out of the addressed slave. Once a slave has been fully addressed, matching both high and low address bytes, the master can issue a Restart and the high address byte with the R/W bit set. The slave logic will then hold the clock and prepare to clock out data.

After a full match with R/W clear in 10-bit mode, a prior match flag is set and maintained. Until a Stop condition, a high address with R/W clear or a high address match fails.
27.3.8 START/STOP CONDITION
interrupt masking
The SSPCON3<SCIE> and SSPCON3<PCIE> bits can enable the generation of an interrupt in slave modes that do not typically support this function. These bits will have no effect on slave modes where interrupt on Start and Stop detect are already enabled.

FIGURE 27-4: \( \textbf{I^2C} \text{ START AND STOP CONDITIONS} \)

27.3.9 ACKNOWLEDGE SEQUENCE
The 9th SCL pulse for any transferred byte in \( \textbf{I^2C} \) is dedicated as an Acknowledge. It allows receiving devices to respond back to the transmitter by pulling the SDA line low. The transmitter must release control of the line during this time to shift in the response. The Acknowledge (\( \text{ACK} \)) is an active-low signal, pulling the SDA line low indicates to the transmitter that the device has received the transmitted data and is ready to receive more.

The result of an \( \text{ACK} \) is placed in the SSPCON2<ACKSTAT> bit.

Slave software, when the AHEN and DHEN bits are set, allows the user to set the \( \text{ACK} \) value sent back to the transmitter. The SSPCON2<ACKDT> bit is set/cleared to determine the response.

Slave hardware will generate an \( \text{ACK} \) response if the SSPCON3<AHEN> and SSPCON3<DHEN> bits are clear.

There are certain conditions where an \( \text{ACK} \) will not be sent by the slave. If the SSPSTAT<BF> bit or the SSPCON1<SSPOV> bit are set when a byte is received, an \( \text{ACK} \) will not be sent.

When the module is addressed, after the 8th falling edge of SCL on the bus, the SSPCON3<ACKTIM> bit is set. The ACKTIM bit indicates the acknowledge time of the active bus. The ACKTIM Status bit is only active when the AHEN bit or DHEN bit is enabled.
27.4 \( ^2 \text{C SLAVE MODE OPERATION} \)

The MSSP Slave mode operates in one of the four modes selected in the SSPCON1<SSPM> bits. The modes can be divided into 7-bit and 10-bit Addressing mode. 10-bit Addressing mode operates the same as 7-bit, with some additional overhead for handling the larger addresses.

Modes with Start and Stop bit interrupts operate the same as the other modes. The exception is the SSPIF bit getting set upon detection of a Start, Restart or Stop condition.

27.4.1 SLAVE MODE ADDRESSES, SSPADD

The SSPADD register contains the Slave mode address. The first byte received after a Start or Restart condition is compared against the value stored in this register. If the byte matches, the value is loaded into the SSPBUF register and an interrupt is generated. If the value does not match, the module goes idle and no indication is given to the software that anything happened.

The SSPMSK register affects the address matching process. See Section 27.4.10 “SSPMSKx Register” for more information.

27.4.2 SECOND SLAVE MODE ADDRESS, SSPADD2

The SSPADD2 register contains a second Slave mode address. To enable the use of this second Slave mode address, bit 0 must be set. The first byte received after a Start or Restart condition is compared against the value stored in this register. If the byte matches, the value is loaded into the SSPBUF register and an interrupt is generated. If the value does not match, the module goes Idle and no indication is given to the software that anything happened.

The SSPMSK2 register affects the address matching process. See Section 27.4.10 “SSPMSKx Register” for more information.

27.4.2.1 \( ^2 \text{C Slave 7-Bit Addressing Mode} \)

In 7-bit Addressing mode, the LSb of the received data byte is ignored when determining if there is an address match.

27.4.2.2 \( ^2 \text{C Slave 10-Bit Addressing Mode} \)

In 10-bit Addressing mode, the first received byte is compared to the binary value of 1 1 1 1 0 A9 A8 0. A9 and A8 are the two MSb of the 10-bit address and stored in bits 2 and 1 in the SSPADDx register.

After the acknowledge of the high byte, the UA bit is set and SCL is held low until the user updates SSPADDx with the low address. The low address byte is clocked in and all eight bits are compared to the low address value in SSPADDx. Even if there is no address match, SSPIF and UA are set and SCL is held low until SSPADDx is updated to receive a high byte again. When SSPADDx is updated, the UA bit is cleared. This ensures the module is ready to receive the high address byte on the next communication.

A high and low address match as a write request is required at the start of all 10-bit addressing communication. A transmission can be initiated by issuing a Restart once the slave is addressed and clocking in the high address with the R/W bit set. The slave hardware will then acknowledge the read request and prepare to clock out data. This is only valid for a slave after it has received a complete high and low address byte match.

27.4.3 SLAVE RECEPTION

When the R/W bit of a matching received address byte is clear, the SSPSTAT<R/W> bit is cleared. The received address is loaded into the SSPBUF register and acknowledged.

When an overflow condition exists for a received address, then a Not Acknowledge is given. An overflow condition is defined as either SSPSTAT<BF> bit or bit SSPCON1<SSPOV> bit is set. The SSPCON3<BOEN> bit modifies this operation. For more information, see Register 27-5.

An MSSP interrupt is generated for each transferred data byte. Flag bit, SSPIF, must be cleared by software.

When the SSPCON2<SEN> bit is set, SCL will be held low (clock stretch) following each received byte. The clock must be released by setting the SSPCON1<CKP> bit, except sometimes in 10-bit mode.
27.4.3.1 7-Bit Addressing Reception

This section describes a standard sequence of events for the MSSP module configured as an I^C slave in 7-bit Addressing mode, all decisions made by hardware or software and their effect on reception. Figures 27-6 and 27-7 are used as a visual reference for this description.

This is a step-by-step process of what typically must be done to accomplish I^C communication.

1. Start bit detected.
2. SSPSTAT<S> bit is set; SSPIF is set if Interrupt-on-Start detect is enabled.
3. Matching address with R/W bit clear is received.
4. The slave pulls SDA low, sending an ACK to the master, and sets SSPIF bit.
5. Software clears the SSPIF bit.
6. Software reads received address from SSPBUF, clearing the BF flag.
7. If SEN = 1, slave software sets CKP bit to release the SCL line.
8. The master clocks out a data byte.
9. Slave drives SDA low, sending an ACK to the master, and sets SSPIF bit.
10. Software clears SSPIF.
11. Software reads the received byte from SSPBUF, clearing BF.
12. Steps 8–12 are repeated for all received bytes from the master.

27.4.3.2 7-Bit Reception with AHEN and DHEN

Slave device reception with AHEN and DHEN set operates the same as without these options, with extra interrupts and clock stretching added after the 8th falling edge of SCL. These additional interrupts allow the slave software to decide whether it wants to ACK the receive address or data byte, rather than the hardware. This functionality adds support for PMBus that was not present on previous versions of this module.

This list describes the steps that need to be taken by slave software to use these options for I^C communication. Figure 27-8 displays a module using both address and data holding. Figure 27-9 includes the operation with the SSPCON2<SEN> bit set.

1. SSPSTAT<S> bit is set; SSPIF is set if interrupt on Start detect is enabled.
2. Matching address with R/W bit clear is clocked in. SSPIF is set and CKP cleared after the 8th falling edge of SCL.
3. Slave clears the SSPIF.
4. Slave can look at the SSPCON3<ACKTIM> bit to determine if the SSPIF was after or before the ACK.
5. Slave reads the address value from SSPBUF, clearing the BF flag.
6. Slave sets ACK value clocked out to the master by setting ACKDT.
7. Slave releases the clock by setting CKP.
8. SSPxIF is set after an ACK, not after a NACK.
9. If SEN = 1 the slave hardware will stretch the clock after the ACK.
10. Slave clears SSPIF.

Note: SSPIF is still set after the 9th falling edge of SCL even if there is no clock stretching and BF has been cleared. Only if NACK is sent to master is SSPIF not set.

11. SSPIF set and CKP cleared after 8th falling edge of SCL for a received data byte.
12. Slave looks at SSPCON3<ACKTIM> bit to determine the source of the interrupt.
13. Slave reads the received data from SSPBUF clearing BF.
14. Steps 7–14 are the same for each received data byte.
15. Communication is ended by either the slave sending an ACK = 1 or the master sending a Stop condition. If a Stop is sent and Interrupt on Stop Detect is disabled, the slave will only know by polling the SSTSTAT<P> bit.

- **BF**: No interrupt after if NACK from slave
27.4.4  SLAVE TRANSMISSION

When the R/W bit of the incoming address byte is set and an address match occurs, the SSPSTAT<R/W> bit is set. The received address is loaded into the SSPBUF register and an ACK pulse is sent by the slave on the 9th bit.

Following the ACK, slave hardware clears the CKP bit and the SCL pin is held low (see Section 27.4.7 “Clock Stretching” for more details). By stretching the clock, the master will be unable to assert another clock pulse until the slave is done preparing the transmit data.

The transmit data must be loaded into the SSPBUF register which also loads the SSPSR register. Then the SCL pin should be released by setting the SSPCON1<CKP> bit. The eight data bits are shifted out on the falling edge of the SCL input. This ensures that the SDA signal is valid during the SCL high time.

The ACK pulse from the master-receiver is latched on the rising edge of the 9th SCL input pulse. This ACK value is copied to the SSPCON2<ACKSTAT> bit. If ACKSTAT is set (NACK), then the data transfer is complete. In this case, when the NACK is latched by the slave, the slave goes idle and waits for another occurrence of the Start bit. If the SDA line was low (ACK), the next transmit data must be loaded into the SSPBUF register. Again, the SCL pin must be released by setting the CKP bit.

An MSSP interrupt is generated for each data transfer byte. The SSPIF bit must be cleared by software and the SSPSTAT register is used to determine the status of the byte. The SSPIF bit is set on the falling edge of the 9th clock pulse.

27.4.4.1 Slave Mode Bus Collision

A slave receives a Read request and begins shifting data out on the SDA line. If a bus collision is detected and the SSPCON3<SBCDE> bit is set, the PIR<BCLIF> bit is set. Once a bus collision is detected, the slave goes Idle and waits to be addressed again. User software can use the BCLIF bit to handle a slave bus collision.

27.4.4.2 7-Bit Transmission

A master device can transmit a read request to a slave and then clock data out of the slave. The list below outlines what software for a slave will need to do to accomplish a standard transmission. Figure 27-10 can be used as a reference to this list.

1. Master sends a Start condition on SDA and SCL.
2. SSPSTAT<S> bit is set; SSPIF is set if Interrupt-on-Start detect is enabled.
3. Matching address with R/W bit set is received by the slave setting SSPIF bit.
4. Slave hardware generates an ACK and sets SSPIF.
5. SSPIF bit is cleared by user.
6. Software reads the received address from SSPBUF, clearing BF.
7. R/W is set so CKP was automatically cleared after the ACK.
8. The slave software loads the transmit data into SSPBUF.
9. CKP bit is set releasing SCL, allowing the master to clock the data out of the slave.
10. SSPIF is set after the ACK response from the master is loaded into the ACKSTAT register.
11. SSPIF bit is cleared.
12. The slave software checks the ACKSTAT bit to see if the master wants to clock out more data.

Note 1: If the master ACKs, the clock will be stretched.

2: ACKSTAT is the only bit updated on the rising edge of SCL (9th) rather than the falling.

13. Steps 9-13 are repeated for each transmitted byte.
14. If the master sends a NACK, the clock is not held, but SSPIF is still set.
15. The master sends a Restart condition or a Stop.
16. The slave is no longer addressed.
**FIGURE 27-10: I²C SLAVE, 7-BIT ADDRESS, TRANSMISSION (AHEN = 0)**

27.4.4.3 7-Bit Transmission with Address Hold Enabled

Setting the SSPCON3<AHEN> bit enables additional clock stretching and interrupt generation after the 8th falling edge of a received matching address. Once a matching address has been clocked in, CKP is cleared and the SSPIF interrupt is set.

Figure 27-11 displays a standard waveform of a 7-bit Address Slave Transmission with AHEN enabled.

1. Bus starts idle.
2. Master sends Start condition; the SSPSTAT<S> bit is set; SSPIF is set if Interrupt-on-Start detect is enabled.
3. Master sends matching address with R/W bit set. After the 8th falling edge of the SCL line, the CKP bit is cleared and SSPIF interrupt is generated.
4. Slave software clears SSPIF.
5. Slave software reads SSPCON3<ACKTIM> bit and SSPSTAT<R/W> and SSPSTAT<D/A> bits to determine the source of the interrupt.
6. Slave reads the address value from the SSPBUF register clearing the BF bit.
7. Slave software decides from this information if it wishes to ACK or NACK and sets SSPCON2<ACKDT> bit accordingly.
8. Slave sets the CKP bit releasing SCL.
9. Master clocks in the ACK value from the slave.
10. Slave hardware automatically clears the CKP bit and sets SSPIF after the ACK if the R/W bit is set.
11. Slave software clears SSPIF.
12. Slave loads value to transmit to the master into SSPBUF setting the BF bit.

**Note:** SSPBUF cannot be loaded until after the ACK.

13. Slave sets CKP bit releasing the clock.
14. Master clocks out the data from the slave and sends an ACK value on the 9th SCL pulse.
15. Slave hardware copies the ACK value into the SSPCON2<ACKSTAT> bit.
16. Steps 10–15 are repeated for each byte transmitted to the master from the slave.
17. If the master sends a NACK, the slave releases the bus, allowing the master to send a Stop and end the communication.

**Note:** Master must send a NACK on the last byte to ensure that the slave releases the SCL line to receive a Stop.
FIGURE 27-11: **I²C SLAVE, 7-BIT ADDRESS, TRANSMISSION (AHEN = 1)**

- **SDA**: Receiving Address
  - Received address is read from SSPBUF
  - Slave clears ACKDT to ACK address
  - ACKTIM is set on 8th falling edge of SCL

- **SCL**: R/W
  - Master releases SDAx to slave for ACK sequence

- **SSPIF**: Cleared by software
- **BF**:
  - ACKDT is automatically cleared after 8th falling edge of SCL
  - BF is automatically cleared after 8th falling edge of SCL

- **ACKDT**: Master’s ACK response is copied to SSPSTAT
  - Clearing by software, releases SCL
  - CKP not cleared after NACK

- **ACKSTAT**: Master sends Stop condition
- **CKP**: When AHEN = 1;
  - CKP is cleared by hardware after receiving matching address.
  - Set by software, releases SCL

- **ACKTIM**: When AHEN = 1;
  - CKP is always cleared after ACK

- **R/W**: Master releases SDAx to slave for ACK sequence

- **D/A**:
27.4.5 SLAVE MODE 10-BIT ADDRESS RECEPTION

This section describes a standard sequence of events for the MSSP module configured as an I2C slave in 10-bit Addressing mode.

Figure 27-12 is used as a visual reference for this description.

This is a step-by-step process of what must be done by slave software to accomplish I2C communication.

1. Bus starts idle.
2. Master sends Start condition; SSPSTAT<S> bit is set; SSPIF is set if Interrupt-on-Start detect is enabled.
3. Master sends matching high address with R/W bit clear; SSPSTAT<UA> bit is set.
4. Slave sends ACK and SSPIF is set.
5. Software clears the SSPIF bit.
6. Software reads received address from SSPBUF, clearing the BF flag.
7. Slave loads low address into SSPADDx, releasing SCL.
8. Master sends matching low-address byte to slave; UA bit is set.

Note: Updates to the SSPADDx register are not allowed until after the ACK sequence.

9. Slave sends ACK and SSPIF is set.

Note: If the low address does not match, SSPIF and UA are still set so that the slave software can set SSPADDx back to the high address. BF is not set because there is no match. CKP is unaffected.

10. Slave clears SSPIF.
11. Slave reads the received matching address from SSPBUF clearing BF.
12. Slave loads high address into SSPADD.
13. Master clocks a data byte to the slave and clocks out the slave’s ACK on the 9th SCL pulse; SSPIF is set.
14. If SSPCON2<SEN> bit is set, CKP is cleared by hardware and the clock is stretched.
15. Slave clears SSPIF.
16. Slave reads the received byte from SSPBUF clearing BF.
17. If SEN is set, the slave sets CKP to release the SCL.
18. Steps 13–17 repeat for each received byte.
19. Master sends Stop to end the transmission.

27.4.6 10-BIT ADDRESSING WITH ADDRESS OR DATA HOLD

Reception using 10-bit addressing with AHEN or DHEN set is the same as with 7-bit modes. The only difference is the need to update the SSPADDx register using the UA bit. All functionality, specifically when the CKP bit is cleared and the SCL line is held low, are the same.

Figure 27-13 can be used as a reference of a slave in 10-bit addressing with AHEN set.

Figure 27-14 shows a standard waveform for a slave transmitter in 10-bit Addressing mode.
FIGURE 27-12: I^2C SLAVE, 10-BIT ADDRESS, RECEPTION (SEN = 1, AHEN = 0, DHEN = 0)
FIGURE 27-13: \(^2\text{C Slave, 10-Bit Address, Reception (SEN = 0, AHEN = 1, DHEN = 0)}\)

![Diagram showing I²C slave reception process with 10-bit address.](image-url)
FIGURE 27-14: I²C SLAVE, 10-BIT ADDRESS, TRANSMISSION (SEN = 0, AHEN = 0, DHEN = 0)

- **SDA**: Receiving Address
- **SCL**: Receiving Second Address Byte
- **SSPIF**: Master sends Restart event
- **BF**: Master sends NA CK
- **UA**: Master sends Stop condition
- **CKP**: SA indicates SSPADD must be updated
- **ACKSTAT**: When R/W = 1; CKP is cleared on
- **R/W**: ACK = 1; Master’s NACK is copied
- **D/A**: Indicates an address has been received

- **SSPBUF loaded with received address**: Set by hardware
- **Cleared by software**: Cleared by software
- **Set by hardware**: Set by hardware
- **Received address is read from SSPBUF**: Data to transmit is loaded into SSPBUF
- **High address is loaded back into SSPADD**: After SSPADD is read, UA is cleared and SCL is released
- **CKP is cleared on 9th falling edge of SCL**: UA indicates SSPADD has been received
- **R/W is copied from the matching address byte**: R/W is copied from the matching address byte
27.4.7 CLOCK STRETCHING

Clock stretching occurs when a device on the bus holds the SCL line low, effectively pausing communication. The slave may stretch the clock to allow more time to handle data or prepare a response for the master device. A master device is not concerned with stretching, as anytime it is active on the bus and not transferring data it is stretching. Any stretching done by a slave is invisible to the master software and handled by the hardware that generates SCL.

The SSPCON1<CKP> bit is used to control stretching in software. Any time the CKP bit is cleared, the module will wait for the SCL line to go low and then hold it. Setting CKP will release SCL and allow more communication.

27.4.7.1 Normal Clock Stretching

Following an ACK, if the SSPSTAT<R/W> bit is set, causing a read request, the slave hardware will clear CKP. This allows the slave time to update SSPBUF with data to transfer to the master. If the SSPCON2<SEN> bit is set, the slave hardware will always stretch the clock after the ACK sequence. Once the slave is ready, CKP is set by software and communication resumes.

Note 1: The BF bit has no effect on whether the clock will be stretched or not. This is different than previous versions of the module that would not stretch the clock or clear CKP, if SSPBUF was read before the 9th falling edge of SCL.

2: Previous versions of the module did not stretch the clock for a transmission if SSPBUF was loaded before the 9th falling edge of SCL. It is now always cleared for read requests.

27.4.7.2 10-Bit Addressing Mode

In 10-bit Addressing mode, when the UA bit is set, the clock is always stretched. This is the only time the SCL is stretched without CKP being cleared. SCL is released immediately after a write to SSPADDx.

Note: Previous versions of the module did not stretch the clock if the second address byte did not match.

27.4.7.3 Byte NACKing

When SSPCON3<AHEN> bit is set, CKP is cleared by the hardware after the 8th falling edge of SCL for a received matching address byte. When SSPCON3<DHEN> bit is set, CKP is cleared after the 8th falling edge of SCL for received data.

Stretching after the 8th falling edge of SCL allows the slave to look at the received address or data and decide if it wants to ACK the received data.

27.4.8 CLOCK SYNCHRONIZATION AND THE CKP BIT

Any time the CKP bit is cleared, the module will wait for the SCL line to go low and then hold it. However, clearing the CKP bit will not assert the SCL output low until the SCL output is already sampled low. Therefore, the CKP bit will not assert the SCL line until an external I2C master device has already asserted the SCL line. The SCL output will remain low until the CKP bit is set and all other devices on the I2C bus have released SCL. This ensures that a write to the CKP bit will not violate the minimum high time requirement for SCL (see Figure 27-15).

FIGURE 27-15: CLOCK SYNCHRONIZATION TIMING
27.4.9 GENERAL CALL ADDRESS SUPPORT

The addressing procedure for the I²C bus is such that the first byte after the Start condition usually determines which device will be the slave addressed by the master device. The exception is the general call address, which can address all devices. When this address is used, all devices will, in theory, respond with an acknowledge.

The general call address is a reserved address in the I²C protocol, defined as address 0x00. When the SSPCON2<GCEN> bit is set, the slave module will automatically ACK the reception of this address, regardless of the value stored in SSPADDx. After the slave clocks in an address of all zeros with the R/W bit clear, an interrupt is generated and slave software can read SSPBUF and respond. Figure 27-16 shows a general call reception sequence.

FIGURE 27-16: SLAVE MODE GENERAL CALL ADDRESS SEQUENCE

<td></td>
</tr>
</tbody>
</table>

In 10-bit Address mode, the UA bit will not be set on the reception of the general call address. The slave will prepare to receive the second byte as data, just as it would in the 7-bit mode.

If the SSPCON3<AHEN> bit register is set, just as with any other address reception, the slave hardware will stretch the clock after the 8th falling edge of SCL. The slave must then set its ACKDT value and release the clock with communication progressing as it would normally.

27.4.10 SSPMSKX REGISTER

An SSP Mask (SSPMSKx) register (Registers 27-6 and 27-8) is available in I²C Slave mode as a mask for the value held in the SSPSRx register during an address comparison operation. A zero (‘0’) bit in the SSPMSKx register has the effect of making the corresponding bit of the received address a "don’t care".

This register is reset to all ‘1’s upon any Reset condition and, therefore, has no effect on standard SSP operation until written with a mask value.

The SSP Mask register is active during:

- 7-bit Address mode: address compare of A<7:1>
- 10-bit Address mode: address compare of A<7:0> only. The SSP mask has no effect during the reception of the first (high) byte of the address.
27.5 \textbf{I}^{2}C \textbf{Master Mode}

Master mode is enabled by setting and clearing the appropriate SSPCON1<SSPM> bits and by setting the SSPEN bit. In Master mode, the SDA and SCK pins must be configured as inputs. The MSSP peripheral hardware will override the output driver TRIS controls when necessary, to drive the pins low.

Master mode of operation is supported by interrupt generation on the detection of the Start and Stop conditions. The Stop (P) and Start (S) bits are cleared from a Reset or when the MSSP module is disabled. Control of the I^2C bus may be taken when the P bit is set or the bus is Idle.

In Firmware Controlled Master mode, user code conducts all I^2C bus operations based on Start and Stop bit condition detection. Start and Stop condition detection is the only active circuitry in this mode. All other communication is done by the user software directly manipulating the SDA and SCL lines.

The following events will cause the SSP Interrupt Flag bit, SSPIF, to be set (SSP interrupt, if enabled):

- Start condition detected
- Stop condition detected
- Data transfer byte transmitted/received
- Acknowledge transmitted/received
- Repeated Start generated

\begin{itemize}
  \item \textbf{Note 1:} The MSSP module, when configured in I^2C Master mode, does not allow queuing of events. For instance, the user is not allowed to initiate a Start condition and immediately write the SSPBUF register to initiate transmission before the Start condition is complete. In this case, the SSPBUF will not be written to and the WCOL bit will be set, indicating that a write to the SSPBUF did not occur.

  \item \textbf{Note 2:} When in Master mode, Start/Stop detection is masked and an interrupt is generated when the SEN/PEN bit is cleared and the generation is complete.
\end{itemize}

27.5.1 \textbf{I}^{2}C \textbf{MASTER MODE OPERATION}

The master device generates all of the serial clock pulses and the Start and Stop conditions. A transfer is ended with a Stop condition or with a Repeated Start condition. Since the Repeated Start condition is also the beginning of the next serial transfer, the I^2C bus will not be released.

In Master Transmitter mode, serial data is output through SDA, while SCL outputs the serial clock. The first byte transmitted contains the slave address of the receiving device (7 bits) and the Read/Write (R/W) bit. In this case, the R/W bit will be logic ‘0’. Serial data is transmitted eight bits at a time. After each byte is transmitted, an Acknowledge bit is received. Start and Stop conditions are output to indicate the beginning and the end of a serial transfer.

In Master Receive mode, the first byte transmitted contains the slave address of the transmitting device (7 bits) and the R/W bit. In this case, the R/W bit will be logic ‘1’. Thus, the first byte transmitted is a 7-bit slave address followed by a ‘1’ to indicate the receive bit. Serial data is received via SDA, while SCL outputs the serial clock. Serial data is received eight bits at a time. After each byte is received, an Acknowledge bit is transmitted. Start and Stop conditions indicate the beginning and the end of transmission.

A Baud Rate Generator is used to set the clock frequency output on SCL. See Section 27.6 “Baud Rate Generator” for more details.

27.5.2 \textbf{CLOCK ARBITRATION}

Clock arbitration occurs when the master, during any receive, transmit or Repeated Start/Stop condition, releases the SCL pin (SCL allowed to float high). When the SCL pin is allowed to float high, the Baud Rate Generator (BRG) is suspended from counting until the SCL pin is actually sampled high. When the SCL pin is sampled high, the Baud Rate Generator is reloaded with the contents of SSPADD<7:0> and begins counting. This ensures that the SCL high time will always be at least one BRG rollover count in the event that the clock is held low by an external device (Figure 27-17).
27.5.3 WCOL STATUS FLAG

If the user writes the SSPBUF when a Start, Restart, Stop, Receive or Transmit sequence is in progress, the WCOL is set and the contents of the buffer are unchanged (the write does not occur). Any time the WCOL bit is set, it indicates that an action on SSPBUF was attempted while the module was not Idle.

**Note:** Because queuing of events is not allowed, writing to the lower five bits in the SSPCON2 register is disabled until the Start condition is complete.

27.5.4 I2C MASTER MODE START CONDITION TIMING

To initiate a Start condition, the user sets the Start Enable (SEN) bit in the SSPCON2 register. If the SDA and SCL pins are sampled high, the Baud Rate Generator is reloaded with the contents of SSPADD<7:0> and starts its count. If SCL and SDA are both sampled high when the Baud Rate Generator times out (TBRG), the SDA pin is driven low. The action of the SDA being driven low while SCL is high is the Start condition and causes the SSPSTAT<S> bit to be set. Following this, the Baud Rate Generator is reloaded with the contents of SSPADD<7:0> and resumes its count. When the Baud Rate Generator times out (TBRG), the SSPCON2<SEN> bit will be automatically cleared by hardware; the Baud Rate Generator is suspended, leaving the SDA line held low and the Start condition is complete.

**Note 1:** If at the beginning of the Start condition the SDA and SCL pins are already sampled low, or if during the Start condition the SCL line is sampled low before the SDA line is driven low, a bus collision occurs, the Bus Collision Interrupt Flag, BCLIF, is set, the Start condition is aborted and the I2C module is reset into its Idle state.

2: The Philips I2C Specification states that a bus collision cannot occur on a Start.
27.5.5  **I^2C MASTER MODE REPEATED START CONDITION TIMING**

A Repeated Start condition occurs when the SSPCON2<RSEN> bit is programmed high and the master state machine is no longer active. When the RSEN bit is set, the SCL pin is asserted low. When the SCL pin is sampled low, the Baud Rate Generator is loaded and begins counting. The SDA pin is released (brought high) for one Baud Rate Generator count (T\text{BRG}). When the Baud Rate Generator times out, if SDA is sampled high, the SCL pin will be deasserted (brought high). When SCL is sampled high, the Baud Rate Generator is reloaded and begins counting. SDA and SCL must be sampled high for one T\text{BRG}. This action is then followed by the assertion of the SDA pin (SDA = 0) for one T\text{BRG} while SCL is high. SCL is asserted low. Following this, the SSPCON2<RSEN> bit will be automatically cleared and the Baud Rate Generator will not be reloaded, leaving the SDA pin held low. As soon as a Start condition is detected on the SDA and SCL pins, the SSPSTAT<S> bit will be set. The SSPIF bit will not be set until the Baud Rate Generator has timed out.

**FIGURE 27-19: REPEAT START CONDITION WAVEFORM**

- **Note 1:** If RSEN is programmed while any other event is in progress, it will not take effect.
- **2:** A bus collision during the Repeated Start condition occurs if:
  - SDA is sampled low when SCL goes from low-to-high.
  - SCL goes low before SDA is asserted low. This may indicate that another master is attempting to transmit a data '1'.

![Repeat Start Condition Waveform Diagram]
27.5.6  I2C MASTER MODE
TRANSMISSION

Transmission of a data byte, a 7-bit address or the other half of a 10-bit address is accomplished by simply writing a value to the SSPBUF register. This action will set the Buffer Full (BF) flag bit and will allow the Baud Rate Generator to begin counting and start the next transmission. Each bit of address/data will be shifted out onto the SDA pin after the falling edge of SCL is asserted. SCL is held low for one Baud Rate Generator rollover count (TBRG). Data should be valid before SCL is released high. When the SCL pin is released high, it is held that way for TBRG. The data on the SDA pin must remain stable for that duration and some hold time after the next falling edge of SCL. After the 8th bit is shifted out (the falling edge of the 8th clock), the BF flag is cleared and the master releases the SDA. This allows the slave device being addressed to respond with an ACK bit during the 9th bit time if an address match occurred or if data was received properly. The status of ACK is written into the ACKSTAT bit on the rising edge of the 9th clock. If the master receives an Acknowledge, the Acknowledge Status (ACKSTAT) bit is cleared. If not, the bit is set. After the 9th clock, the SSPIF bit is set and the master clock (Baud Rate Generator) is suspended until the next data byte is loaded into the SSPBUF, leaving SCL low and SDA unchanged (Figure 27-20).

After the write to the SSPBUF, each bit of the address will be shifted out on the falling edge of SCL until all seven address bits and the R/W bit are completed. On the falling edge of the 8th clock, the master will release the SDA pin, allowing the slave to respond with an Acknowledge. On the falling edge of the 9th clock, the master will sample the SDA pin to see if the address was recognized by a slave. The status of the ACK bit is loaded into the ACKSTAT<bit> on the rising edge of the 9th clock. Following the falling edge of the 9th clock transmission of the address, the SSPBUF is set, the BF flag is cleared and the Baud Rate Generator is turned off until another write to the SSPBUF takes place, holding SCL low and allowing SDA to float.

27.5.6.1  BF Status Flag

In Transmit mode, the SSPSTAT<BF> bit is set when the CPU writes to SSPBUF and is cleared when all eight bits are shifted out.

27.5.6.2  WCOL Status Flag

If the user writes the SSPBUF when a transmit is already in progress (i.e., SSPSR is still shifting out a data byte), the WCOL is set and the contents of the buffer are unchanged (the write does not occur). WCOL must be cleared by software before the next transmission.

27.5.6.3  ACKSTAT Status Flag

In Transmit mode, the SSPCON2<ACKSTAT> bit is cleared when the slave has sent an Acknowledge (ACK = 0) and is set when the slave does Not Acknowledge (ACK = 1). A slave sends an Acknowledge when it has recognized its address (including a general call) or when the slave has properly received its data.

27.5.6.4  Typical Transmit Sequence

1. The user generates a Start condition by setting the SSPCON2<SEN> bit.
2. SSPIF is set by hardware on completion of the Start.
3. SSPIF is cleared by software.
4. The MSSP module will wait the required start time before any other operation takes place.
5. The user loads the SSPBUF with the slave address to transmit.
6. Address is shifted out the SDA pin until all eight bits are transmitted. Transmission begins as soon as SSPBUF is written to.
7. The MSSP module shifts in the ACK bit from the slave device and writes its value into the SSPCON2<ACKSTAT> bit.
8. The MSSP module generates an interrupt at the end of the 9th clock cycle by setting the SSPIF bit.
9. The user loads the SSPBUF with eight bits of data.
10. Data is shifted out the SDA pin until all eight bits are transmitted.
11. The MSSP module shifts in the ACK bit from the slave device and writes its value into the SSPCON2<ACKSTAT> bit.
12. Steps 8-11 are repeated for all transmitted data bytes.
13. The user generates a Stop or Restart condition by setting the SSPCON2<PEN> or SSPCON2<RSEN> bits. Interrupt is generated once the Stop/Restart condition is complete.
FIGURE 27-20: \( \text{i}^\text{2} \text{C} \) MASTER MODE WAVEFORM (TRANSMISSION, 7 OR 10-BIT ADDRESS)

- **BF (SSPSTAT<0>)**: Buffer Full Flag
- **SEN**: Start/Stop
- **R/W**: Read/Write

**Transmitting Data or Second Half of 10-bit Address**
- Start condition begins
- SEN = 0
- Transmit Address to Slave
- SSPBUF written with 7-bit address and R/W
- SCL held low while CPU responds to SSPIF
- ACK = 0
- From slave, clear ACKSTAT bit SSPCON2<6>
- SSPBUF is written
- SSPBUF is written by software

**Clear by software service routine from SSP interrupt**
- SEN cleared by hardware
- After Start condition, SEN cleared by hardware
27.5.7 \textit{I}^2\textit{C} MASTER MODE RECEPTION

Master mode reception is enabled by programming the Receive Enable (RCEN) bit in the SSPCON2 register.

\begin{itemize}
\item \textbf{Note:} The MSSP module must be in an Idle state before the RCEN bit is set or the RCEN bit will be disregarded.
\end{itemize}

The Baud Rate Generator begins counting and on each rollover the state of the SCL pin changes (high-to-low/low-to-high) and data is shifted into the SSPSR. After the falling edge of the 8th clock, the receive enable flag is automatically cleared, the contents of the SSPSR are loaded into the SSPBUF, the BF flag bit is set, the SSPIF flag bit is set and the Baud Rate Generator is suspended from counting, holding SCL low. The MSSP is now in Idle state awaiting the next command. When the buffer is read by the CPU, the BF flag bit is automatically cleared. The user can then send an Acknowledge bit at the end of reception by setting the Acknowledge Sequence Enable (ACKEN) bit in the SSPCON2 register.

27.5.7.1 BF Status Flag

In receive operation, the BF bit is set when an address or data byte is loaded into SSPBUF from SSPSR. It is cleared when the SSPBUF register is read.

27.5.7.2 SSPOV Status Flag

In receive operation, the SSPOV bit is set when eight bits are received into the SSPSR and the BF flag bit is already set from a previous reception.

27.5.7.3 WCOL Status Flag

If the user writes the SSPBUF when a receive is already in progress (i.e., SSPSR is still shifting in a data byte), the WCOL bit is set and the contents of the buffer are unchanged (the write does not occur).

27.5.7.4 Typical Receive Sequence

1. The user generates a Start condition by setting the SSPCON2<SEN> bit.
2. SSPIF is set by hardware on completion of the Start.
3. SSPIF is cleared by software.
4. The user writes SSPBUF with the slave address to transmit and the R/W bit set.
5. Address is shifted out the SDA pin until all eight bits are transmitted. Transmission begins as soon as SSPBUF is written to.
6. The MSSP module shifts in the \textbf{ACK} bit from the slave device and writes its value into the SSPCON2<ACKSTAT> bit.
7. The MSSP module generates an interrupt at the end of the 9th clock cycle by setting the SSPIF bit.
8. User sets the SSPCON2<RCEN> bit and the master clocks in a byte from the slave.
9. After the 8th falling edge of SCL, SSPIF and BF are set.
10. Master clears SSPIF and reads the received byte from SSPBUF, clears BF.
11. Master sets \textbf{ACK} value sent to slave in SSPCON2<ACKDT> bit and initiates the \textbf{ACK} by setting the ACKEN bit.
12. Master’s \textbf{ACK} is clocked out to the slave and SSPIF is set.
13. The user clears SSPIF.
14. Steps 8–13 are repeated for each received byte from the slave.
15. Master sends a \textbf{NACK} or Stop to end communication.

\textbf{Note:} The MSSP module must be in an Idle state before the RCEN bit is set or the RCEN bit will be disregarded.
FIGURE 27-21: \( \text{I}^2\text{C} \) MASTER MODE WAVEFORM (RECEPTION, 7-BIT ADDRESS)

Write to SSPCON2<0> (SEN = 1), begin Start condition

- Write to SSPBUF occurs here, start XMIT
- Transmit Address to slave

Master configured as a receiver by programming SSPCON2<3> (RCEN = 1)

- ACK from slave
- Receiving Data from slave

- RCEN cleared automatically
- ACK from master
- SDA = ACKDT
- RCEN cleared automatically
- Master configured as a receiver by programming SSPCON2<3> (RCEN = 1)

SSPIF

- SDA = 0, SCLx = 1 while CPU responds to SSPxIF
- cleared by software
- Set SSPIF interrupt at end of receive
- Last bit is shifted into SSPSR and contents are unloaded into SSPBUF
- SSPOV
- SSPOV is set because SSPBUF is still full

ACKEN

- RCEN cleared automatically
- ACK from master
- SDA = ACKDT
- RCEN cleared automatically

BF (SSPSTAT<0>)
27.5.8 ACKNOWLEDGE SEQUENCE TIMING

An Acknowledge sequence is enabled by setting the Acknowledge Sequence Enable (ACKEN) bit in the SSPCON2 register. When this bit is set, the SCL pin is pulled low and the contents of the Acknowledge data bit are presented on the SDA pin. If the user wishes to generate an Acknowledge, then the ACKDT bit should be cleared. If not, the user should set the ACKDT bit before starting an Acknowledge sequence. The Baud Rate Generator then counts for one rollover period (TBRG) and the SCL pin is deasserted (pulled high). When the SCL pin is sampled high (clock arbitration), the Baud Rate Generator counts for TBRG. The SCL pin is then pulled low. Following this, the ACKEN bit is automatically cleared, the Baud Rate Generator is turned off and the MSSP module then goes into Idle mode (Figure 27-22).

27.5.8.1 WCOL Status Flag

If the user writes the SSPBUF when an Acknowledge sequence is in progress, then WCOL is set and the contents of the buffer are unchanged (the write does not occur).

FIGURE 27-22: ACKNOWLEDGE SEQUENCE WAVEFORM

![](image)

Note: $T_{BRG}$ = one Baud Rate Generator period.

27.5.9 STOP CONDITION TIMING

A Stop bit is asserted on the SDA pin at the end of a receive/transmit by setting the Stop Sequence Enable (PEN) in the SSPCON2 register. At the end of a receive/transmit, the SCL line is held low after the falling edge of the 9th clock. When the PEN bit is set, the master will assert the SDA line low. When the SDA line is sampled low, the Baud Rate Generator is reloaded and counts down to ‘0’. When the Baud Rate Generator times out, the SCL pin will be brought high and, one $T_{BRG}$ (Baud Rate Generator rollover count) later, the SDA pin will be deasserted. When the SDA pin is sampled high while SCL is high, the SSPSTAT<0> bit is set. A $T_{BRG}$ later, the PEN bit is cleared and the SSPIF bit is set (Figure 27-23).

27.5.9.1 WCOL Status Flag

If the user writes the SSPBUF when a Stop sequence is in progress, then the WCOL bit is set and the contents of the buffer are unchanged (the write does not occur).
27.5.10 SLEEP OPERATION
While in Sleep mode, the \(^2\text{C}\) slave module can receive addresses or data and, when an address match or complete byte transfer occurs, wakes the processor from Sleep (if the MSSP interrupt is enabled).

27.5.11 EFFECTS OF A RESET
A Reset disables the MSSP module and terminates the current transfer.

27.5.12 MULTI-MASTER MODE
In Multi-Master mode, the interrupt generation on the detection of the Start and Stop conditions allows the determination of when the bus is free. The Stop (P) and Start (S) bits are cleared from a Reset or when the MSSP module is disabled. Control of the \(^2\text{C}\) bus may be taken when the P bit in the SSPSTAT register is set or the bus is Idle, with both the S and P bits clear. When the bus is busy, enabling the SSP interrupt will generate the interrupt when the Stop condition occurs.

In multi-master operation, the SDA line must be monitored for arbitration to see if the signal level is the expected output level. This check is performed by hardware with the result placed in the BCLIF bit.

The states where arbitration can be lost are:
- Address Transfer
- Data Transfer
- A Start Condition
- A Repeated Start Condition
- An Acknowledge Condition

27.5.13 MULTI-MASTER COMMUNICATION, BUS COLLISION AND BUS ARBITRATION
Multi-Master mode support is achieved by bus arbitration. When the master outputs address/data bits onto the SDA pin, arbitration takes place when the master outputs a '1' on SDA, by letting SDA float high and another master asserts a '0'. When the SCL pin floats high, data should be stable. If the expected data on SDA is a '1' and the data sampled on the SDA pin is '0', then a bus collision has taken place. The master will set the Bus Collision Interrupt Flag (BCLIF) and reset the \(^2\text{C}\) bus to its Idle state (Figure 27-24).

If a transmit was in progress when the bus collision occurred, the transmission is halted, the BF flag is cleared, the SDA and SCL lines are deasserted and the SSPBUF can be written to. When the user services the bus collision Interrupt Service Routine and if the \(^2\text{C}\) bus is free, the user can resume communication by asserting a Start condition.

If a Start, Repeated Start, Stop or Acknowledge condition was in progress when the bus collision occurred, the condition is aborted, the SDA and SCL lines are deasserted and the respective control bits in the SSPCON2 register are cleared. When the user services the bus collision Interrupt Service Routine and if the \(^2\text{C}\) bus is free, the user can resume communication by asserting a Start condition.

The master will continue to monitor the SDA and SCL pins. If a Stop condition occurs, the SSPIF bit will be set.

A write to the SSPBUF will start the transmission of data at the first data bit, regardless of where the transmitter left off when the bus collision occurred.

In Multi-Master mode, the interrupt generation on the detection of Start and Stop conditions allows the determination of when the bus is free. Control of the \(^2\text{C}\) bus can be taken when the P bit is set in the SSPSTAT register or the bus is Idle and the S and P bits are cleared.
27.5.13.1 Bus Collision During a Start Condition

During a Start condition, a bus collision occurs if:

a) SDA or SCL are sampled low at the beginning of the Start condition (Figure 27-25).

b) SCL is sampled low before SDA is asserted low (Figure 27-26).

During a Start condition, both the SDA and the SCL pins are monitored.

If the SDA pin is already low or the SCL pin is already low, then all of the following occur:

- the Start condition is aborted
- the BCLIF flag is set
- the MSSP module is reset to its Idle state (Figure 27-25)

The Start condition begins with the SDA and SCL pins deasserted. When the SDA pin is sampled high, the Baud Rate Generator is loaded and counts down. If the SCL pin is sampled low while SDA is high, a bus collision occurs because it is assumed that another master is attempting to drive a data '1' during the Start condition.

If the SDA pin is sampled low during this count, the BRG is reset and the SDA line is asserted early (Figure 27-27). If, however, a '1' is sampled on the SDA pin, the SDA pin is asserted low at the end of the BRG count. The Baud Rate Generator is then reloaded and counts down to zero; if the SCL pin is sampled as '0' during this time, a bus collision does not occur. At the end of the BRG count, the SCL pin is asserted low.

Note: The reason that bus collision is not a factor during a Start condition is that no two bus masters can assert a Start condition at the exact same time. Therefore, one master will always assert SDA before the other. This condition does not cause a bus collision because the two masters must be allowed to arbitrate the first address following the Start condition. If the address is the same, arbitration must be allowed to continue into the data portion, Repeated Start or Stop conditions.
FIGURE 27-25: BUS COLLISION DURING START CONDITION (SDA ONLY)

- SDA goes low before the SEN bit is set. Set BCLIF, S bit and SSPIF set because SDA = 0, SCL = 1.
- SEN cleared automatically because of bus collision. SSP module reset into Idle state.
- SDA sampled low before Start condition. Set BCLIF, S bit and SSPIF set because SDA = 0, SCL = 1.
- SSPIF and BCLIF are cleared by software.

FIGURE 27-26: BUS COLLISION DURING START CONDITION (SCL = 0)

- SEN
- BCLIF
- S
- SSPIF
**FIGURE 27-27: BRG RESET DUE TO SDA ARBITRATION DURING START CONDITION**

- **SDA**: SDA = 0, SCL = 1, less than \( T_{BRG} \) → Set S → Set SSPIF
- **SDA**: SDA pulled low by other master → Reset BRG and assert SDAx
- **SCL**: SCL = 0, SCLx pulled low after BRG time out
- **SEN**: Set SEN, enable Start sequence if SDA = 1, SCL = 1 → ‘0’
- **BCLIF**: Interrupts cleared by software

Other conditions include:
- **SDAX = 0, SCL = 1**, set SSPIF
- **SDA = 0**
27.5.13.2 Bus Collision during a Repeated Start Condition

During a Repeated Start condition, a bus collision occurs if:

a) A low level is sampled on SDA when SCL goes from low level to high level.

b) SCL goes low before SDA is asserted low, indicating that another master is attempting to transmit a data '1'.

When the user releases SDA and the pin is allowed to float high, the BRG is loaded with SSPADD and counts down to zero. The SCL pin is then deasserted and, when sampled high, the SDA pin is sampled.

If SDA is low, a bus collision has occurred (i.e., another master is attempting to transmit a data '0', Figure 27-28). If SDA is sampled high, the BRG is reloaded and begins counting. If SDA goes from high-to-low before the BRG times out, no bus collision occurs because no two masters can assert SDA at exactly the same time.

If SCL goes from high-to-low before the BRG times out and SDA has not already been asserted, a bus collision occurs. In this case, another master is attempting to transmit a data '1' during the Repeated Start condition (see Figure 27-29.)

If, at the end of the BRG time out, both SCL and SDA are still high, the SDA pin is driven low and the BRG is reloaded and begins counting. At the end of the count, regardless of the status of the SCL pin, the SCL pin is driven low and the Repeated Start condition is complete.

**FIGURE 27-28: BUS COLLISION DURING A REPEATED START CONDITION (CASE 1)**

SCL goes low before SDA, set BCLIF. Release SDA and SCL.
Interrupt cleared by software.
27.5.13.3 Bus Collision During a Stop Condition

Bus collision occurs during a Stop condition if:

a) After the SDA pin has been deasserted and allowed to float high, SDA is sampled low after the BRG has timed out.

b) After the SCL pin is deasserted, SCL is sampled low before SDA goes high.

The Stop condition begins with SDA asserted low. When SDA is sampled low, the SCL pin is allowed to float. When the pin is sampled high (clock arbitration), the Baud Rate Generator is loaded with SSPADD and counts down to 0. After the BRG times out, SDA is sampled. If SDA is sampled low, a bus collision has occurred. This is due to another master attempting to drive a data ‘0’ (Figure 27-30). If the SCL pin is sampled low before SDA is allowed to float high, a bus collision occurs. This is another case of another master attempting to drive a data ‘0’ (Figure 27-31).

**Legend:**  
— = unimplemented, read as ‘0’. Shaded cells are not used by the MSSP module in I²C mode.  
* Page provides register information.
27.6 BAUD RATE GENERATOR

The MSSP module has a Baud Rate Generator available for clock generation in I2C Master mode. The Baud Rate Generator (BRG) reload value is placed in the SSPADD register. When a write occurs to SSPBUF, the Baud Rate Generator will automatically begin counting down.

Once the given operation is complete, the internal clock will automatically stop counting and the clock pin will remain in its last state.

An internal signal “Reload” in Figure 27-32 triggers the value from SSPADD to be loaded into the BRG counter. This occurs twice for each oscillation of the module clock line. The logic dictating when the reload signal is asserted depends on the mode the MSSP is being operated in.

Table 27-2 demonstrates clock rates based on instruction cycles and the BRG value loaded into SSPADD.

EQUATION 27-1:

\[ F_{CLOCK} = \frac{F_{OSC}}{(SSPADD + 1)(4)} \]

FIGURE 27-32: BAUD RATE GENERATOR BLOCK DIAGRAM

Note: Values of 0x00, 0x01 and 0x02 are not valid for SSPADD when used as a Baud Rate Generator for I2C. This is an implementation limitation.

TABLE 27-2: MSSP CLOCK RATE W/BRG

Legend:
R = Readable bit  W = Writable bit  U = Unimplemented bit, read as ‘0’
-n = Value at POR  ‘1’ = Bit is set  ‘0’ = Bit is cleared  x = Bit is unknown

- **bit 7 SMP**: Data Input Sample bit
  - 1 = Slew rate control disabled for standard speed mode (100 kHz and 1 MHz)
  - 0 = Slew rate control enabled for high speed mode (400 kHz)

- **bit 6 CKE**: Clock Edge Select bit
  - 1 = Enable input logic so that thresholds are compliant with SMBus specification
  - 0 = Disable SMBus specific inputs

- **bit 5 D/A**: Data/Address bit
  - 1 = Indicates that the last byte received or transmitted was data
  - 0 = Indicates that the last byte received or transmitted was address

- **bit 4 P**: Stop bit
  - (This bit is cleared when the MSSP module is disabled, SSPEN is cleared.)
  - 1 = Indicates that a Stop bit has been detected last (this bit is ‘0’ on Reset)
  - 0 = Stop bit was not detected last

- **bit 3 S**: Start bit
  - (This bit is cleared when the MSSP module is disabled, SSPEN is cleared.)
  - 1 = Indicates that a Start bit has been detected last (this bit is ‘0’ on Reset)
  - 0 = Start bit was not detected last

- **bit 2 R/W**: Read/Write bit information
  - This bit holds the R/W bit information following the last address match. This bit is only valid from the address match to the next Start bit, Stop bit or NACK bit.
  - In I²C Slave mode:
    - 1 = Read
    - 0 = Write
  - In I²C Master mode:
    - 1 = Transmit is in progress
    - 0 = Transmit is not in progress
    - OR-ing this bit with SEN, RSEN, PEN, RCEN or ACKEN will indicate if the MSSP is in Idle mode.

- **bit 1 UA**: Update Address bit (10-bit I²C mode only)
  - 1 = Indicates that the user needs to update the address in the SSPADD register
  - 0 = Address does not need to be updated

- **bit 0 BF**: Buffer Full Status bit
  - Receive:
    - 1 = Receive complete, SSPBUF is full
    - 0 = Receive not complete, SSPBUF is empty
  - Transmit:
    - 1 = Data transmit in progress (does not include the ACK and Stop bits), SSPBUF is full
    - 0 = Data transmit complete (does not include the ACK and Stop bits), SSPBUF is empty

- x = Bit is unknown
- HS = Bit is set by hardware
- C = User cleared

bit 7

WCOL: Write Collision Detect bit

Master mode:
1 = A write to the SSPBUF register was attempted while the I2C conditions were not valid for a transmission to be started
0 = No collision

Slave mode:
1 = The SSPBUF register is written while it is still transmitting the previous word (must be cleared in software)
0 = No collision

bit 6

SSPOV: Receive Overflow Indicator bit

1 = A byte is received while the SSPBUF register is still holding the previous byte. SSPOV is a “don’t care” in Transmit mode (must be cleared in software).
0 = No overflow

bit 5

SSPEN: Synchronous Serial Port Enable bit

In both modes, when enabled, these pins must be properly configured as input or output
1 = Enables the serial port and configures the SDA and SCL pins as the source of the serial port pins
0 = Disables serial port and configures these pins as I/O port pins

bit 4

CKP: Clock Polarity Select bit

In I2C Slave mode:
1 = Enable clock
0 = Holds clock low (clock stretch). (Used to ensure data setup time.)

In I2C Master mode:
Unused in this mode

bit 3-0

SSPM<3:0>: Synchronous Serial Port Mode Select bits

0000 = Reserved
0001 = Reserved
0010 = Reserved
0011 = Reserved
0100 = Reserved
0101 = Reserved
0110 = I2C Slave mode, 7-bit address
0111 = I2C Slave mode, 10-bit address
1000 = I2C Master mode, clock = FOSC/(4 x (SSPADD+1))\(^{(3)}\)
1001 = Reserved
1010 = Reserved
1011 = I2C firmware controlled Master mode (Slave idle)
1100 = Reserved
1101 = Reserved
1110 = I2C Slave mode, 7-bit address with Start and Stop bit interrupts enabled
1111 = I2C Slave mode, 10-bit address with Start and Stop bit interrupts enabled

Note 1: In Master mode, the overflow bit is not set since each new reception (and transmission) is initiated by writing to the SSPBUF register.

2: When enabled, the SDA and SCL pins must be configured as inputs.

3: SSPADD values of 0, 1 or 2 are not supported for I2C Mode.

- **x** = Bit is unknown
- **H** = Bit is set by hardware  
- **S** = User set  
- **-n/n** = Value at POR/Value at all other resets

### bit 7
- **GCEN**: General Call Enable bit (in I²C Slave mode only)
  - 1 = Enable interrupt when a general call address (0x00 or 00h) is received in the SSPSR
  - 0 = General call address disabled

### bit 6
- **ACKSTAT**: Acknowledge Status bit
  - 1 = Acknowledge was not received
  - 0 = Acknowledge was received

### bit 5
- **ACKDT**: Acknowledge Data bit
  - **In Receive mode:**
    - Value transmitted when the user initiates an Acknowledge sequence at the end of a receive
    - 1 = Not Acknowledge
    - 0 = Acknowledge

### bit 4
- **ACKEN**: Acknowledge Sequence Enable bit (in I²C Master mode only)
  - **In Master Receive mode:**
    - 1 = Initiate Acknowledge sequence on SDA and SCL pins and transmit ACKDT data bit. Automatically cleared by hardware.
    - 0 = Acknowledge sequence Idle

### bit 3
- **RCEN**: Receive Enable bit (in I²C Master mode only)
  - 1 = Enables Receive mode for I²C
  - 0 = Receive Idle

### bit 2
- **PEN**: Stop Condition Enable bit (in I²C Master mode only)
  - **SCK Release Control:**
    - 1 = Initiate Stop condition on SDA and SCL pins. Automatically cleared by hardware
    - 0 = Stop condition Idle

### bit 1
- **RSEN**: Repeated Start Condition Enabled bit (in I²C Master mode only)
  - 1 = Initiate Repeated Start condition on SDA and SCL pins. Automatically cleared by hardware
  - 0 = Repeated Start condition Idle

### bit 0
- **SEN**: Start Condition Enabled bit (in I²C Master mode only)
  - **In Master mode:**
    - 1 = Initiate Start condition on SDA and SCL pins. Automatically cleared by hardware
    - 0 = Start condition Idle
  - **In Slave mode:**
    - 1 = Clock stretching is enabled for both slave transmit and slave receive (stretch enabled)
    - 0 = Clock stretching is disabled

### Note 1:
For bits ACKEN, RCEN, PEN, RSEN, SEN: If the I²C module is not in the Idle mode, this bit may not be set (no spooling) and the SSPBUF may not be written (or writes to the SSPBUF are disabled).

U = Unimplemented bit, read as ‘0’

-n/n = Value at POR/Value at all other resets

1 = Bit is set
0 = Bit is cleared
x = Bit is unknown

bit 7  **ACKTIM**: Acknowledge Time Status bit

- 1 = Indicates the **I**2**C** bus is in an Acknowledge sequence, set on the 8th falling edge of SCL clock
- 0 = Not an Acknowledge sequence, cleared on the 9th rising edge of SCL clock

bit 6  **PCIE**: Stop Condition Interrupt Enable bit

- 1 = Enable interrupt on detection of Stop condition
- 0 = Stop detection interrupts are disabled

bit 5  **SCIE**: Start Condition Interrupt Enable bit

- 1 = Enable interrupt on detection of Start or Restart conditions
- 0 = Start detection interrupts are disabled

bit 4  **BOEN**: Buffer Overwrite Enable bit

In **I**2**C** Master mode:

- This bit is ignored.

In **I**2**C** Slave mode:

- 1 = SSPBUF is updated and ACK is generated for a received address/data byte, ignoring the state of the SSPOV bit only if the BF bit = 0.
- 0 = SSPBUF is only updated when SSPOV is clear

bit 3  **SDAHT**: SDA Hold Time Selection bit

- 1 = Minimum of 300 ns hold time on SDA after the falling edge of SCL
- 0 = Minimum of 100 ns hold time on SDA after the falling edge of SCL

bit 2  **SBCDE**: Slave Mode Bus Collision Detect Enable bit (**I**2**C** Slave mode only)

- If on the rising edge of SCL, SDA is sampled low when the module is outputting a high state, the BCLIF bit in the PIR2 register is set, and bus goes Idle
- 1 = Enable slave bus collision interrupts
- 0 = Slave bus collision interrupts are disabled

bit 1  **AHEN**: Address Hold Enable bit (**I**2**C** Slave mode only)

- 1 = Following the 8th falling edge of SCL for a matching received address byte; CKP bit in the SSPCON1 register will be cleared and the SCL will be held low.
- 0 = Address holding is disabled

bit 0  **DHEN**: Data Hold Enable bit (**I**2**C** Slave mode only)

- 1 = Following the 8th falling edge of SCL for a received data byte; slave hardware clears the CKP bit in the SSPCON1 register and SCL is held low.
- 0 = Data holding is disabled

**Note 1**: This bit has no effect in slave modes where Start and Stop condition detection is explicitly listed as enabled.

**Note 2**: The ACKTIM Status bit is only active when the AHEN bit or DHEN bit is set.

bit 0  ADD2<0>: SSPADD2 Enable bit.
1 = Enable address matching with SSPADD2
0 = Disable address matching with SSPADD2
28.0 IN-CIRCUIT SERIAL PROGRAMMING™ (ICSP™)

ICSP programming allows customers to manufacture circuit boards with unprogrammed devices. Programming can be done after the assembly process, allowing the device to be programmed with the most recent firmware or a custom firmware. Five pins are needed for ICSP programming:
- ICSPCLK
- ICSPDAT
- MCLR
- VDD
- VSS

In Program/Verify mode, the Program Memory, User IDs and the Configuration Words are programmed through serial communications. The ICSPDAT pin is a bidirectional I/O used for transferring the serial data and the ICSPCLK pin is the clock input. The device is placed into a Program/Verify mode by holding the ICSPDAT and ICSPCLK pins low, while raising the MCLR pin from $V_L$ to $V_{IH}$.

28.1 Common Programming Interfaces

Connection to a target device is typically done through an ICSP header. A commonly found connector on development tools is the RJ-11 in the 6P6C (6-pin, 6-connector) configuration. See Figure 28-1.

**FIGURE 28-1: ICD RJ-11 STYLE CONNECTOR INTERFACE**

Another connector often found in use with the PICkit™ programmers is a standard 6-pin header with 0.1 inch spacing. Refer to Figure 28-2.

**FIGURE 28-2: PICKit™ PROGRAMMER-STYLE CONNECTOR INTERFACE**

*The 6-pin header (0.100" spacing) accepts 0.025" square pins.*
For additional interface recommendations, refer to your specific device programmer manual prior to PCB design.

It is recommended that isolation devices be used to separate the programming pins from other circuitry. The type of isolation is highly dependent on the specific application and may include devices, such as resistors, diodes or even jumpers. See Figure 28-3 for more information.

28.2 In-Circuit Debugger

In-circuit debugging requires access to the ICDCLK, ICDDATA and MCLR pins. These pins are only available on the MCP19119 device.
29.0 INSTRUCTION SET SUMMARY

The MCP19118/19 instruction set is highly orthogonal and is comprised of three basic categories:

- **Byte-oriented** operations
- **Bit-oriented** operations
- **Literal and control** operations

Each instruction is a 14-bit word divided into an **opcode**, which specifies the instruction type, and one or more **operands**, which further specify the operation of the instruction. The formats for each of the categories are presented in Figure 29-1, while the various opcode fields are summarized in Table 29-1.

Table 29-2 lists the instructions recognized by the MPASM™ assembler.

For **byte-oriented** instructions, ‘f’ represents a file register designator and ‘d’ represents a destination designator. The file register designator specifies which file register is to be used by the instruction.

The destination designator specifies where the result of the operation is to be placed. If ‘d’ is zero, the result is placed in the W register. If ‘d’ is one, the result is placed in the file register specified in the instruction.

For **bit-oriented** instructions, ‘b’ represents a bit field designator, which selects the bit affected by the operation, while ‘f’ represents the address of the file in which the bit is located.

For **literal and control** operations, ‘k’ represents an 8-bit or 11-bit constant, or literal value.

One instruction cycle consists of four oscillator periods; for an oscillator frequency of 4 MHz, this gives a normal instruction execution time of 1 µs. All instructions are executed within a single instruction cycle, unless a conditional test is true, or the program counter is changed as a result of an instruction. When this occurs, the execution takes two instruction cycles, with the second cycle executed as an **NOP**.

All instruction examples use the format ‘0xhh’ to represent a hexadecimal number, where ‘h’ signifies a hexadecimal digit.

29.1 Read-Modify-Write Operations

Any instruction that specifies a file register as part of the instruction performs a Read-Modify-Write (RMW) operation. The register is read, the data is modified, and the result is stored according to either the instruction or the destination designator ‘d’. A read operation is performed on a register even if the instruction writes to that register.

For example, a **CLR F PORTA** instruction will read PORTGPA, clear all the data bits, then write the result back to PORTGPA. This example would have the unintended consequence of clearing the condition that set the IOCF flag.

</tbody>
</table>

**Note 1:** When an I/O register is modified as a function of itself (e.g., MOVF PORTA, l), the value used will be that value present on the pins themselves. For example, if the data latch is ‘1’ for a pin configured as input and is driven low by an external device, the data will be written back with a ‘0’.

**Note 2:** If this instruction is executed on the TMR0 register (and where applicable, d = 1), the prescaler will be cleared if assigned to the Timer0 module.

**Note 3:** If the Program Counter (PC) is modified, or a conditional test is true, the instruction requires two cycles. The second cycle is executed as an NOP.
29.2 Instruction Descriptions

**ADDLW** Add literal and W

| Syntax: | [label] ADDLW k |
| Operands: | 0 ≤ k ≤ 255 |
| Operation: | (W) + k → (W) |
| Status Affected: | C, DC, Z |
| Description: | The contents of the W register are added to the eight-bit literal ‘k’ and the result is placed in the W register. |

**ADDWF** Add W and f

| Syntax: | [label] ADDWF f,d |
| Operands: | 0 ≤ f ≤ 127 |
| d ∈ [0, 1] |
| Operation: | (W) + (f) → (destination) |
| Status Affected: | C, DC, Z |
| Description: | Add the contents of the W register with register ‘f’. If ‘d’ is ‘0’, the result is stored in the W register. If ‘d’ is ‘1’, the result is stored back in register ‘f’. |

**ANDLW** AND literal with W

| Syntax: | [label] ANDLW k |
| Operands: | 0 ≤ k ≤ 255 |
| Operation: | (W) .AND. (k) → (W) |
| Status Affected: | Z |
| Description: | The contents of W register are AND'ed with the eight-bit literal ‘k’. The result is placed in the W register. |

**ANDWF** AND W with f

| Syntax: | [label] ANDWF f,d |
| Operands: | 0 ≤ f ≤ 127 |
| d ∈ [0, 1] |
| Operation: | (W) .AND. (f) → (destination) |
| Status Affected: | Z |
| Description: | AND the W register with register ‘f’. If ‘d’ is ‘0’, the result is stored in the W register. If ‘d’ is ‘1’, the result is stored back in register ‘f’. |

**BCF** Bit Clear f

| Syntax: | [label] BCF f,b |
| Operands: | 0 ≤ f ≤ 127 |
| 0 ≤ b ≤ 7 |
| Operation: | 0 → (f<b>) |
| Status Affected: | None |
| Description: | Bit ‘b’ in register ‘f’ is cleared. |

**BSF** Bit Set f

| Syntax: | [label] BSF f,b |
| Operands: | 0 ≤ f ≤ 127 |
| 0 ≤ b ≤ 7 |
| Operation: | 1 → (f<b>) |
| Status Affected: | None |
| Description: | Bit ‘b’ in register ‘f’ is set. |

**BTFSC** Bit Test f, Skip if Clear

| Syntax: | [label] BTFSC f,b |
| Operands: | 0 ≤ f ≤ 127 |
| 0 ≤ b ≤ 7 |
| Operation: | skip if (f<b>) = 0 |
| Status Affected: | None |
| Description: | If bit ‘b’ in register ‘f’ is ‘1’, the next instruction is executed. If bit ‘b’ in register ‘f’ is ‘0’, the next instruction is discarded, and an NOP is executed instead, making this a two-cycle instruction. |
BTFSS Bit Test f, Skip if Set
Syntax: \[ label \] BTFSS f,b
Operands: 0 ≤ f ≤ 127
0 ≤ b < 7
Operation: skip if \((f<b)> = \ 1\)
Status Affected: None
Description: If bit ‘b’ in register ‘f’ is ‘0’, the next instruction is executed.
If bit ‘b’ is ‘1’, then the next instruction is discarded and an NOP is executed instead, making this a two-cycle instruction.

CALL Call Subroutine
Syntax: \[ label \] CALL k
Operands: 0 ≤ k ≤ 2047
Operation: (PC)+ 1 → TOS,
k → PC<10:0>,
(PCLATH<4:3>) → PC<12:11>
Status Affected: None
Description: Call Subroutine. First, return address (PC + 1) is pushed onto the stack. The eleven-bit immediate address is loaded into PC bits <10:0>. The upper bits of the PC are loaded from PCLATH. CALL is a two-cycle instruction.

CLRF Clear f
Syntax: \[ label \] CLRF f
Operands: 0 ≤ f ≤ 127
Operation: 00h → (f)
1 → Z
Status Affected: Z
Description: The contents of register ‘f’ are cleared and the Z bit is set.

CLRW Clear W
Syntax: \[ label \] CLRW
Operands: None
Operation: 00h → (W)
1 → Z
Status Affected: Z
Description: W register is cleared. Zero bit (Z) is set.

CLRWDT Clear Watchdog Timer
Syntax: \[ label \] CLRWDT
Operands: None
Operation: 00h → WDT
0 → WDT prescaler,
1 → TO
1 → PD
Status Affected: TO, PD
Description: CLRWDT instruction resets the Watchdog Timer. It also resets the prescaler of the WDT. Status bits TO and PD are set.

COMF Complement f
Syntax: \[ label \] COMF f,d
Operands: 0 ≤ f ≤ 127
d ∈ \[0,1\]
Operation: \((f) → (destination)\)
Status Affected: Z
Description: The contents of register ‘f’ are complemented. If ‘d’ is ‘0’, the result is stored in W. If ‘d’ is ‘1’, the result is stored back in register ‘f’.

DECF Decrement f
Syntax: \[ label \] DECF f,d
Operands: 0 ≤ f ≤ 127
d ∈ \[0,1\]
Operation: \((f) - 1 → (destination)\)
Status Affected: Z
Description: Decrement register ‘f’. If ‘d’ is ‘0’, the result is stored in the W register. If ‘d’ is ‘1’, the result is stored back in register ‘f’. 
<table>
<thead>
<tr>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>DECFSZ</strong></td>
<td>Decrement f, Skip if 0</td>
</tr>
<tr>
<td>Syntax:</td>
<td>([ label ]) DECFSZ  f,d</td>
</tr>
</tbody>
</table>
| Operands:   | \(0 \leq f \leq 127\)  
             | \(d \in [0,1]\) |
| Operation:  | \((f) - 1 \rightarrow (\text{destination});\)  
             | skip if result = 0 |
| Status Affected: | None |
| Description: | The contents of register 'f' are decremented. If 'd' is '0', the result is placed in the W register. If 'd' is '1', the result is placed back in register 'f'. If the result is '1', the next instruction is executed. If the result is '0', an NOP is executed instead, making it a two-cycle instruction. |

| **INCFSZ**  | Increment f, Skip if 0 |
| Syntax:     | \([ label ]\) INCFSZ  f,d |
| Operands:   | \(0 \leq f \leq 127\)  
             | \(d \in [0,1]\) |
| Operation:  | \((f) + 1 \rightarrow (\text{destination});\)  
             | skip if result = 0 |
| Status Affected: | None |
| Description: | The contents of register 'f' are incremented. If 'd' is '0', the result is placed in the W register. If 'd' is '1', the result is placed back in register 'f'. If the result is '1', the next instruction is executed. If the result is '0', an NOP is executed instead, making it a two-cycle instruction. |

| **GOTO**    | Unconditional Branch |
| Syntax:     | \([ label ]\) GOTO  k |
| Operands:   | \(0 \leq k \leq 2047\) |
| Operation:  | \(k \rightarrow \text{PC}<10:0>\)  
             | \(\text{PCLATH}<4:3> \rightarrow \text{PC}<12:11>\) |
| Status Affected: | None |
| Description: | GOTO is an unconditional branch. The eleven-bit immediate value is loaded into PC bits <10:0>. The upper bits of PC are loaded from PCLATH<4:3>. GOTO is a two-cycle instruction. |

| **IORLW**   | Inclusive OR literal with W |
| Syntax:     | \([ label ]\) IORLW  k |
| Operands:   | \(0 \leq k \leq 255\) |
| Operation:  | \((W) .OR. k \rightarrow (W)\) |
| Status Affected: | Z |
| Description: | The contents of the W register are OR'ed with the eight-bit literal 'k'. The result is placed in the W register. |

| **INCF**    | Increment f |
| Syntax:     | \([ label ]\) INCF  f,d |
| Operands:   | \(0 \leq f \leq 127\)  
             | \(d \in [0,1]\) |
| Operation:  | \((f) + 1 \rightarrow (\text{destination})\)  
             | Z |
| Status Affected: | Z |
| Description: | The contents of register 'f' are incremented. If 'd' is '0', the result is placed in the W register. If 'd' is '1', the result is placed back in register 'f'. |

| **IORWF**   | Inclusive OR W with f |
| Syntax:     | \([ label ]\) IORWF  f,d |
| Operands:   | \(0 \leq f \leq 127\)  
             | \(d \in [0,1]\) |
| Operation:  | \((W) .OR. (f) \rightarrow (\text{destination})\)  
             | Z |
| Status Affected: | Z |
| Description: | Inclusive OR the W register with register 'f'. If 'd' is '0', the result is placed in the W register. If 'd' is '1', the result is placed back in register 'f'. |
### MOVF Move f

**Syntax:** \([ \text{label} ] \)    MOVF   f,d  
**Operands:** \(0 \leq f \leq 127\)  
\(d \in [0,1]\)  
**Operation:** \((f) \rightarrow (\text{dest})\)  
**Status Affected:** Z  
**Description:** The contents of register 'f' is moved to a destination dependent upon the status of 'd'. If \(d = 0\), destination is W register. If \(d = 1\), the destination is file register 'f' itself. \(d = 1\) is useful to test a file register since Status flag Z is affected.

**Words:** 1  
**Cycles:** 1  
**Example:**  
Before Instruction  
After Instruction  
\(W = \text{value in FSR register}\)  
\(Z = 1\)

### MOVWF Move W to f

**Syntax:** \([ \text{label} ] \)    MOVWF f  
**Operands:** \(0 \leq f \leq 127\)  
**Operation:** \((W) \rightarrow (f)\)  
**Status Affected:** None  
**Description:** Move data from W register to register 'f'.

**Words:** 1  
**Cycles:** 1  
**Example:**  
Before Instruction  
\(\text{OP\_W} = 0xFF\)  
\(F = 0x4F\)  
After Instruction  
\(\text{OP\_W} = 0x4F\)  
\(F = 0x4F\)

### MOVLW Move literal to W

**Syntax:** \([ \text{label} ] \)    MOVLW k  
**Operands:** \(0 \leq k \leq 255\)  
**Operation:** \(k \rightarrow (W)\)  
**Status Affected:** None  
**Description:** The eight-bit literal 'k' is loaded into W register. The "don't cares" will assemble as '0's.

**Words:** 1  
**Cycles:** 1  
**Example:**  
Before Instruction  
\(W = 0x5A\)  
After Instruction  
\(W = 0x5A\)

### NOP No Operation

**Syntax:** \([ \text{label} ] \)    NOP  
**Operands:** None  
**Operation:** No operation  
**Status Affected:** None  
**Description:** No operation.

**Words:** 1  
**Cycles:** 1  
**Example:**  
Before Instruction  
\(\text{OP\_W} = 0xFF\)  
\(F = 0x4F\)  
After Instruction  
\(\text{OP\_W} = 0x4F\)  
\(F = 0x4F\)
**RETFIE**  Return from Interrupt

- **Syntax:** \([ \text{label} ] \) RETFIE
- **Operands:** None
- **Operation:** TOS \(\rightarrow\) PC, \(1 \rightarrow\) GIE
- **Status Affected:** None
- **Description:** Return from Interrupt. Stack is POPed and Top-of-Stack (TOS) is loaded in the PC. Interrupts are enabled by setting Global Interrupt Enable bit, GIE (INT-CON<7>). This is a two-cycle instruction.
- **Words:** 1
- **Cycles:** 2
- **Example:**

  ```plaintext
  After Interrupt
  PC = TOS
  GIE = 1
  ```

**RETLW**  Return with literal in W

- **Syntax:** \([ \text{label} ] \) RETLW \(k\)
- **Operands:** \(0 \leq k \leq 255\)
- **Operation:** \(k \rightarrow (W);\) TOS \(\rightarrow\) PC
- **Status Affected:** None
- **Description:** The W register is loaded with the eight-bit literal ‘\(k\)’. The program counter is loaded from the top of the stack (the return address). This is a two-cycle instruction.
- **Words:** 1
- **Cycles:** 2
- **Example:**

  ```plaintext
  CALL TABLE; \(W\) contains table offset;value
  GOTO DONE
  
  TABLE
  
  ADDWF PC; \(W = \text{offset}\)
  RETLW k1 ; \text{Begin table}
  RETLW k2 ;
  
  RETLW kn ; \text{End of table}

  DONE
  
  Before Instruction
  \(W = 0x07\)
  
  After Instruction
  \(W = \text{value of } k_8\)
  ```

**RETURN**  Return from Subroutine

- **Syntax:** \([ \text{label} ] \) RETURN
- **Operands:** None
- **Operation:** TOS \(\rightarrow\) PC
- **Status Affected:** None
- **Description:** Return from subroutine. The stack is POPed and the top of the stack (TOS) is loaded into the program counter. This is a two-cycle instruction.
**RLF**

**Rotate Left f through Carry**

Syntax: \[ label \] RLF f,d

Operands: \[ 0 \leq f \leq 127 \]
\[ d \in [0,1] \]

Operation: See description below

Status Affected: C

Description: The contents of register ‘f’ are rotated one bit to the left through the Carry flag. If ‘d’ is ‘0’, the result is placed in the W register. If ‘d’ is ‘1’, the result is stored back in register ‘f’.

Example: RLF REG1,0

Before Instruction
REG1 = 1110
0110
C = 0

After Instruction
REG1 = 1110
0110
W = 1100
1100
C = 1

**RRF**

**Rotate Right f through Carry**

Syntax: \[ label \] RRF f,d

Operands: \[ 0 \leq f \leq 127 \]
\[ d \in [0,1] \]

Operation: See description below

Status Affected: C

Description: The contents of register ‘f’ are rotated one bit to the right through the Carry flag. If ‘d’ is ‘0’, the result is placed in the W register. If ‘d’ is ‘1’, the result is placed back in register ‘f’.

**SLEEP**

**Enter Sleep mode**

Syntax: \[ label \] SLEEP

Operands: None

Operation: 00h \( \rightarrow \) WDT, 0 \( \rightarrow \) WDT prescaler,
1 \( \rightarrow \) TO, 0 \( \rightarrow \) PD

Status Affected: TO, PD

Description: The power-down Status bit, PD is cleared. Time-out Status bit, TO is set. Watchdog Timer and its prescaler are cleared. The processor is put into Sleep mode with the oscillator stopped.

**SUBLW**

**Subtract W from literal**

Syntax: \[ label \] SUBLW k

Operands: \[ 0 \leq k \leq 255 \]

Operation: k - (W) \( \rightarrow \) (W)

Status Affected: C, DC, Z

Description: The W register is subtracted (two’s complement method) from the eight-bit literal ‘k’. The result is placed in the W register.

<table>
<thead>
<tr>
<th>Result</th>
<th>Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>C = 0</td>
<td>W &gt; k</td>
</tr>
<tr>
<td>C = 1</td>
<td>W ≤ k</td>
</tr>
<tr>
<td>DC = 0</td>
<td>W&lt;3:0&gt; &gt; k&lt;3:0&gt;</td>
</tr>
<tr>
<td>DC = 1</td>
<td>W&lt;3:0&gt; ≤ k&lt;3:0&gt;</td>
</tr>
</tbody>
</table>
### SUBWF

**Subtract W from f**

<table>
<thead>
<tr>
<th>Syntax:</th>
<th>[ label ] SUBWF f,d</th>
</tr>
</thead>
<tbody>
<tr>
<td>Operands:</td>
<td>0 ≤ f ≤ 127</td>
</tr>
<tr>
<td></td>
<td>d ∈ [0,1]</td>
</tr>
<tr>
<td>Operation:</td>
<td>(f) - (W) → (destination)</td>
</tr>
<tr>
<td>Status Affected:</td>
<td>C, DC, Z</td>
</tr>
<tr>
<td>Description:</td>
<td>Subtract (two’s complement method) W register from register ‘f’. If ‘d’ is ‘0’, the result is stored in the W register. If ‘d’ is ‘1’, the result is stored back in register ‘f’.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>C = 0</th>
<th>W &gt; f</th>
</tr>
</thead>
<tbody>
<tr>
<td>C = 1</td>
<td>W ≤ f</td>
</tr>
<tr>
<td>DC = 0</td>
<td>W&lt;3:0&gt; &gt; f&lt;3:0&gt;</td>
</tr>
<tr>
<td>DC = 1</td>
<td>W&lt;3:0&gt; ≤ f&lt;3:0&gt;</td>
</tr>
</tbody>
</table>

### XORWF

**Exclusive OR W with f**

<table>
<thead>
<tr>
<th>Syntax:</th>
<th>[ label ] XORWF f,d</th>
</tr>
</thead>
<tbody>
<tr>
<td>Operands:</td>
<td>0 ≤ f ≤ 127</td>
</tr>
<tr>
<td></td>
<td>d ∈ [0,1]</td>
</tr>
<tr>
<td>Operation:</td>
<td>(W) .XOR. (f) → (destination)</td>
</tr>
<tr>
<td>Status Affected:</td>
<td>Z</td>
</tr>
<tr>
<td>Description:</td>
<td>Exclusive OR the contents of the W register with register ‘f’. If ‘d’ is ‘0’, the result is stored in the W register. If ‘d’ is ‘1’, the result is stored back in register ‘f’.</td>
</tr>
</tbody>
</table>

### SWAPF

**Swap Nibbles in f**

<table>
<thead>
<tr>
<th>Syntax:</th>
<th>[ label ] SWAPF f,d</th>
</tr>
</thead>
<tbody>
<tr>
<td>Operands:</td>
<td>0 ≤ f ≤ 127</td>
</tr>
<tr>
<td></td>
<td>d ∈ [0,1]</td>
</tr>
<tr>
<td>Operation:</td>
<td>(f&lt;3:0&gt;) → (destination&lt;7:4&gt;),</td>
</tr>
<tr>
<td></td>
<td>(f&lt;7:4&gt;) → (destination&lt;3:0&gt;)</td>
</tr>
<tr>
<td>Status Affected:</td>
<td>None</td>
</tr>
<tr>
<td>Description:</td>
<td>The upper and lower nibbles of register ‘f’ are exchanged. If ‘d’ is ‘0’, the result is placed in the W register. If ‘d’ is ‘1’, the result is placed in register ‘f’.</td>
</tr>
</tbody>
</table>

### XORLW

**Exclusive OR literal with W**

<table>
<thead>
<tr>
<th>Syntax:</th>
<th>[ label ] XORLW k</th>
</tr>
</thead>
<tbody>
<tr>
<td>Operands:</td>
<td>0 ≤ k ≤ 255</td>
</tr>
<tr>
<td>Operation:</td>
<td>(W) .XOR. k → (W)</td>
</tr>
<tr>
<td>Status Affected:</td>
<td>Z</td>
</tr>
<tr>
<td>Description:</td>
<td>The contents of the W register are XOR’ed with the eight-bit literal ‘k’. The result is placed in the W register.</td>
</tr>
</tbody>
</table>
30.0 DEVELOPMENT SUPPORT

The PIC® microcontrollers (MCU) and dsPIC® digital signal controllers (DSC) are supported with a full range of software and hardware development tools:

- Integrated Development Environment
  - MPLAB® X IDE Software
- Compilers/Assemblers/Linkers
  - MPLAB XC Compiler
  - MPASM™ Assembler
  - MPLINK™ Object Linker/
    MPLIB™ Object Librarian
  - MPLAB Assembler/Linker/Librarian for
    Various Device Families
- Simulators
  - MPLAB X SIM Software Simulator
- Emulators
  - MPLAB REAL ICE™ In-Circuit Emulator
- In-Circuit Debuggers/Programmers
  - MPLAB ICD 3
  - PICkit™ 3
- Device Programmers
  - MPLAB PM3 Device Programmer
- Low-Cost Demonstration/Development Boards,
  Evaluation Kits and Starter Kits
- Third-party Development Tools

30.1 MPLAB X Integrated Development Environment Software

The MPLAB X IDE is a single, unified graphical user interface for Microchip and third-party software, and hardware development tool that runs on Windows®, Linux and Mac OS® X. Based on the NetBeans IDE, MPLAB X IDE is an entirely new IDE with a host of free software components and plug-ins for high-performance application development and debugging. Moving between tools and upgrading from software simulators to hardware debugging and programming tools is simple with the seamless user interface.

With complete project management, visual call graphs, a configurable watch window and a feature-rich editor that includes code completion and context menus, MPLAB X IDE is flexible and friendly enough for new users. With the ability to support multiple tools on multiple projects with simultaneous debugging, MPLAB X IDE is also suitable for the needs of experienced users.

Feature-Rich Editor:

- Color syntax highlighting
- Smart code completion makes suggestions and
  provides hints as you type
- Automatic code formatting based on user-defined
  rules
- Live parsing

User-Friendly, Customizable Interface:

- Fully customizable interface: toolbars, toolbar
  buttons, windows, window placement, etc.
- Call graph window

Project-Based Workspaces:

- Multiple projects
- Multiple tools
- Multiple configurations
- Simultaneous debugging sessions

File History and Bug Tracking:

- Local file history feature
- Built-in support for Bugzilla issue tracker
30.2 MPLAB XC Compilers

The MPLAB XC Compilers are complete ANSI C compilers for all of Microchip’s 8, 16, and 32-bit MCU and DSC devices. These compilers provide powerful integration capabilities, superior code optimization and ease of use. MPLAB XC Compilers run on Windows, Linux or MAC OS X.

For easy source level debugging, the compilers provide debug information that is optimized to the MPLAB X IDE.

The free MPLAB XC Compiler editions support all devices and commands, with no time or memory restrictions, and offer sufficient code optimization for most applications.

MPLAB XC Compilers include an assembler, linker and utilities. The assembler generates relocatable object files that can then be archived or linked with other relocatable object files and archives to create an executable file. MPLAB XC Compiler uses the assembler to produce its object file. Notable features of the assembler include:

- Support for the entire device instruction set
- Support for fixed-point and floating-point data
- Command-line interface
- Rich directive set
- Flexible macro language
- MPLAB X IDE compatibility

30.3 MPASM Assembler

The MPASM Assembler is a full-featured, universal macro assembler for PIC10/12/16/18 MCUs.

The MPASM Assembler generates relocatable object files for the MPLINK Object Linker, Intel® standard HEX files, MAP files to detail memory usage and symbol reference, absolute LST files that contain source lines and generated machine code, and COFF files for debugging.

The MPASM Assembler features include:

- Integration into MPLAB X IDE projects
- User-defined macros to streamline assembly code
- Conditional assembly for multipurpose source files
- Directives that allow complete control over the assembly process

30.4 MPLINK Object Linker/ MPLIB Object Librarian

The MPLINK Object Linker combines relocatable objects created by the MPASM Assembler. It can link relocatable objects from precompiled libraries, using directives from a linker script.

The MPLIB Object Librarian manages the creation and modification of library files of precompiled code. When a routine from a library is called from a source file, only the modules that contain that routine will be linked in with the application. This allows large libraries to be used efficiently in many different applications.

The object link/library features include:

- Efficient linking of single libraries instead of many smaller files
- Enhanced code maintainability by grouping related modules together
- Flexible creation of libraries with easy module listing, replacement, deletion and extraction

30.5 MPLAB Assembler, Linker and Librarian for Various Device Families

MPLAB Assembler produces relocatable machine code from symbolic assembly language for PIC24, PIC32 and dsPIC DSC devices. MPLAB XC Compiler uses the assembler to produce its object file. The assembler generates relocatable object files that can then be archived or linked with other relocatable object files and archives to create an executable file. Notable features of the assembler include:

- Support for the entire device instruction set
- Support for fixed-point and floating-point data
- Command-line interface
- Rich directive set
- Flexible macro language
- MPLAB X IDE compatibility
30.6  MPLAB X SIM Software Simulator

The MPLAB X SIM Software Simulator allows code development in a PC-hosted environment by simulating the PIC MCUs and dsPIC DSCs on an instruction level. On any given instruction, the data areas can be examined or modified and stimuli can be applied from a comprehensive stimulus controller. Registers can be logged to files for further run-time analysis. The trace buffer and logic analyzer display extend the power of the simulator to record and track program execution, actions on I/O, most peripherals and internal registers.

The MPLAB X SIM Software Simulator fully supports symbolic debugging using the MPLAB XC Compilers, and the MPASM and MPLAB Assemblers. The software simulator offers the flexibility to develop and debug code outside of the hardware laboratory environment, making it an excellent, economical software development tool.

30.7  MPLAB REAL ICE In-Circuit Emulator System

The MPLAB REAL ICE In-Circuit Emulator System is Microchip’s next generation high-speed emulator for Microchip Flash DSC and MCU devices. It debugs and programs all 8, 16 and 32-bit MCU, and DSC devices with the easy-to-use, powerful graphical user interface of the MPLAB X IDE.

The emulator is connected to the design engineer’s PC using a high-speed USB 2.0 interface and is connected to the target with either a connector compatible with in-circuit debugger systems (RJ-11) or with the new high-speed, noise tolerant, Low-Voltage Differential Signal (LVDS) interconnection (CAT5).

The emulator is field upgradeable through future firmware downloads in MPLAB X IDE. MPLAB REAL ICE In-circuit emulator offers significant advantages over competitive emulators including full-speed emulation, run-time variable watches, trace analysis, complex breakpoints, logic probes, a ruggedized probe interface and long (up to three meters) interconnection cables.

30.8  MPLAB ICD 3 In-Circuit Debugger System

The MPLAB ICD 3 In-Circuit Debugger System is Microchip’s most cost-effective, high-speed hardware debugger/programmer for Microchip Flash DSC and MCU devices. It debugs and programs PIC Flash microcontrollers and dsPIC DSCs with the powerful, yet easy-to-use graphical user interface of the MPLAB IDE.

The MPLAB ICD 3 In-Circuit Debugger probe is connected to the design engineer’s PC using a high-speed USB 2.0 interface and is connected to the target with a connector compatible with the MPLAB ICD 2 or MPLAB REAL ICE systems (RJ-11). MPLAB ICD 3 supports all MPLAB ICD 2 headers.

30.9  PICkit 3 In-Circuit Debugger/Programmer

The MPLAB PICkit 3 In-Circuit Debugger allows debugging and programming of PIC and dsPIC Flash microcontrollers at a most affordable price point using the powerful graphical user interface of the MPLAB IDE. The MPLAB PICkit 3 In-Circuit Debugger is connected to the design engineer’s PC using a full-speed USB interface and can be connected to the target via a Microchip debug (RJ-11) connector (compatible with MPLAB ICD 3 and MPLAB REAL ICE In-Circuit Emulator). The connector uses two device I/O pins and the Reset line to implement in-circuit debugging and In-Circuit Serial Programming™ (ICSP™).

30.10  MPLAB PM3 Device Programmer

The MPLAB PM3 Device Programmer is a universal, CE compliant device programmer with programmable voltage verification at VDDMIN and VDDMAX for maximum reliability. It features a large LCD display (128 x 64) for menus and error messages, and a modular, detachable socket assembly to support various package types. The ICSP cable assembly is included as a standard item. In Stand-Alone mode, the MPLAB PM3 Device Programmer can read, verify and program PIC devices without a PC connection. It can also set code protection in this mode. The MPLAB PM3 Device Programmer connects to the host PC via an RS-232 or USB cable. The MPLAB PM3 Device Programmer has high-speed communications and optimized algorithms for quick programming of large memory devices, and incorporates an MMC card for file storage and data applications.
30.11 Demonstration/Development Boards, Evaluation Kits and Starter Kits

A wide variety of demonstration, development and evaluation boards for various PIC MCUs and dsPIC DSCs allows quick application development on fully functional systems. Most boards include prototyping areas for adding custom circuitry and provide application firmware and source code for examination and modification.

The boards support a variety of features, including LEDs, temperature sensors, switches, speakers, RS-232 interfaces, LCD displays, potentiometers and additional EEPROM memory.

The demonstration and development boards can be used in teaching environments, for prototyping custom circuits and for learning about various microcontroller applications.

In addition to the PICDEM™ and dsPICDEM™ demonstration/development board series of circuits, Microchip has a line of evaluation kits and demonstration software for analog filter design, KeELOQ® security ICs, CAN, IrDA®, PowerSmart battery management, SEEVAL® evaluation system, Sigma-Delta ADC, flow rate sensing, plus many more.

Also available are starter kits that contain everything needed to experience the specified device. This usually includes a single application and debug capability, all on one board.

Check the Microchip web page (www.microchip.com) for the complete list of demonstration, development and evaluation kits.

30.12 Third-Party Development Tools

Microchip also offers a great collection of tools from third-party vendors. These tools are carefully selected to offer good value and unique functionality.

- Device Programmers and Gang Programmers from companies, such as SoftLog and CCS
- Software Tools from companies, such as Gimpel and Trace Systems
- Protocol Analyzers from companies, such as Saleae and Total Phase
- Demonstration Boards from companies, such as MikroElektronika, Digilent® and Olimex
- Embedded Ethernet Solutions from companies, such as EZ Web Lynx, WIZnet and IPLogika®
31.0 PACKAGING INFORMATION

31.1 Package Marking Information

24-Lead QFN (4x4x0.9 mm) (MCP19118 only)

Example

28-Lead QFN (5x5x0.9 mm) (MCP19119 only)

Example

Legend:

XX...X Customer-specific information
Y Year code (last digit of calendar year)
YY Year code (last 2 digits of calendar year)
WWW Week code (week of January 1 is week ‘01’)
NNN Alphanumeric traceability code
\textsuperscript{e3} RoHS Compliant JEDEC\textsuperscript{®} designator for Matte Tin (Sn)
\textsuperscript{*} This package is RoHS Compliant. The RoHS Compliant JEDEC designator (\textsuperscript{e3}) can be found on the outer packaging for this package.

Note: In the event the full Microchip part number cannot be marked on one line, it will be carried over to the next line, thus limiting the number of available characters for customer-specific information.
24-Lead Plastic Quad Flat, No Lead Package (MJ) – 4x4x0.9 mm Body [QFN]

THE MICROCHIP WEB SITE

Microchip provides online support via our web site at www.microchip.com. This web site is used as a means to make files and information easily available to customers. Accessible by using your favorite Internet browser, the web site contains the following information:

• **Product Support** – Data sheets and errata, application notes and sample programs, design resources, user’s guides and hardware support documents, latest software releases and archived software
• **General Technical Support** – Frequently Asked Questions (FAQ), technical support requests, online discussion groups, Microchip consultant program member listing
• **Business of Microchip** – Product selector and ordering guides, latest Microchip press releases, listing of seminars and events, listings of Microchip sales offices, distributors and factory representatives

CUSTOMER CHANGE NOTIFICATION SERVICE

Microchip’s customer notification service helps keep customers current on Microchip products. Subscribers will receive e-mail notification whenever there are changes, updates, revisions or errata related to a specified product family or development tool of interest.

To register, access the Microchip web site at www.microchip.com. Under “Support”, click on “Customer Change Notification” and follow the registration instructions.

CUSTOMER SUPPORT

Users of Microchip products can receive assistance through several channels:

• Distributor or Representative
• Local Sales Office
• Field Application Engineer (FAE)
• Technical Support

Customers should contact their distributor, representative or Field Application Engineer (FAE) for support. Local sales offices are also available to help customers. A listing of sales offices and locations is included in the back of this document.

**Technical support is available through the web site at:** http://www.microchip.com/support
### PRODUCT IDENTIFICATION SYSTEM

To order or obtain information, e.g., on pricing or delivery, refer to the factory or the listed sales office.

<table>

</tbody>
</table>

#### Examples:

1. a) MCP19118-E/MJ: Extended temperature, 24LD QFN 4x4 package  
   b) MCP19118T-E/MJ: Tape and Reel, Extended temperature, 24LD QFN 4x4 package
2. a) MCP19119-E/MQ: Extended temperature, 28LD QFN 5x5 package  
   b) MCP19119T-E/MQ: Tape and Reel, Extended temperature, 28LD QFN 5x5 package

#### Note 1:
Tape and Reel identifier only appears in the catalog part number description. This identifier is used for ordering purposes and is not printed on the device package. Check with your Microchip Sales Office for package availability with the Tape and Reel option.
NOTICE TO CUSTOMERS

This product is subject to a license from Power-One®, Inc. related to digital power technology (DPT) patents owned by Power-One, Inc. This license does not extend to stand-alone power supply products.
Note the following details of the code protection feature on Microchip devices:

- Microchip products meet the specification contained in their particular Microchip Data Sheet.

- Microchip believes that its family of products is one of the most secure families of its kind on the market today, when used in the intended manner and under normal conditions.

- There are dishonest and possibly illegal methods used to breach the code protection feature. All of these methods, to our knowledge, require using the Microchip products in a manner outside the operating specifications contained in Microchip’s Data Sheets. Most likely, the person doing so is engaged in theft of intellectual property.

- Microchip is willing to work with the customer who is concerned about the integrity of their code.

- Neither Microchip nor any other semiconductor manufacturer can guarantee the security of their code. Code protection does not mean that we are guaranteeing the product as “unbreakable.”

Code protection is constantly evolving. We at Microchip are committed to continuously improving the code protection features of our products. Attempts to break Microchip’s code protection feature may be a violation of the Digital Millennium Copyright Act. If such acts allow unauthorized access to your software or other copyrighted work, you may have a right to sue for relief under that Act.

Information contained in this publication regarding device applications and the like is provided only for your convenience and may be superseded by updates. It is your responsibility to ensure that your application meets with your specifications. Microchip makes no representations or warranties of any kind whether express or implied, written or oral, statutory or otherwise, related to the information, including but not limited to its condition, quality, performance, merchantability or fitness for purpose. Microchip disclaims all liability arising from this information and its use. Use of Microchip devices in life support and/or safety applications is entirely at the buyer’s risk, and the buyer agrees to defend, indemnify and hold harmless Microchip from any and all damages, claims, suits, or expenses resulting from such use. No licenses are conveyed, implicitly or otherwise, under any Microchip intellectual property rights.

**Trademarks**

The Microchip name and logo, the Microchip logo, dsPIC, FlashFlex, flexPWR, JukeBloxx, KEELOGO, KEELOGO logo, Kleer, LANCheck, MediaLB, MOST, MOST logo, MPLAB, OptoLyzr, PIC, PICSTART, PIC® logo, RightTouch, SpyNIC, SST, SST Logo, SuperFlash and UNI/O are registered trademarks of Microchip Technology Incorporated in the U.S.A. and other countries.

The Embedded Control Solutions Company and mTouch are registered trademarks of Microchip Technology Incorporated in the U.S.A.

**QUALITY MANAGEMENT SYSTEM CERTIFIED BY DNV**

ISO/TS 16949

Microchip received ISO/TS-16949:2009 certification for its worldwide headquarters, design and wafer fabrication facilities in Chandler and Tempe, Arizona; Gresham, Oregon and design centers in California and India. The Company’s quality system processes and procedures are for its PIC® MCUs and dsPIC® DSCs, KeelLoc® code hopping devices, Serial EEPROMs, microperipherals, nonvolatile memory and analog products. In addition, Microchip’s quality system for the design and manufacture of development systems is ISO 9001:2000 certified.
