MCP3002

2.7V Dual Channel 10-Bit A/D Converter with SPI Serial Interface

- 10-bit resolution
- ±1 LSB maximum DNL
- ±1 LSB maximum INL
- Analog inputs programmable as single-ended or pseudo-differential pairs
- On-chip sample and hold
- SPI serial interface (modes 0,0 and 1,1)
- Single supply operation: 2.7V - 5.5V
- 200 ksps max sampling rate at VDD = 5V
- 75 ksps max sampling rate at VDD = 2.7V
- Low power CMOS technology:
  - 5 nA typical standby current, 2 µA maximum
  - 550 µA maximum active current at 5V
- Industrial temperature range: -40°C to +85°C
- 8-pin MSOP, PDIP, SOIC and TSSOP packages

Applications
- Sensor Interface
- Process Control
- Data Acquisition
- Battery Operated Systems

Functional Block Diagram

The MCP3002 is a successive approximation 10-bit analog-to-digital (A/D) converter with on-board sample and hold circuitry.

The MCP3002 is programmable to provide a single pseudo-differential input pair or dual single-ended inputs. Differential Nonlinearity (DNL) and Integral Nonlinearity (INL) are both specified at ±1 LSB. Communication with the device is done using a simple serial interface compatible with the SPI protocol. The device is capable of conversion rates of up to 200 ksps at 5V and 75 ksps at 2.7V.

The MCP3002 operates over a broad voltage range, 2.7V to 5.5V. Low-current design permits operation with a typical standby current of 5 nA and a typical active current of 375 µA.

The MCP3002 is offered in 8-pin MSOP, PDIP, TSSOP and 150 mil SOIC packages.

1.0 ELECTRICAL CHARACTERISTICS

Absolute Maximum Ratings †

$V_{DD}$ .................................................................................. 7.0V
All Inputs and Outputs w.r.t. $V_{SS}$         -0.6V to $V_{DD} + 0.6V$
Storage Temperature.....................................-65°C to +150°C
Ambient temperature with power applied.......-65°C to +150°C
ESD Protection On All Pins (HBM)..................≥ 4 kV

† Notice: Stresses above those listed under “Absolute Maximum Ratings” may cause permanent damage to the device. This is a stress rating only and functional operation of the device at those or any other conditions above those indicated in the operational listings of this specification is not implied. Exposure to maximum rating conditions for extended periods may affect device reliability.

ELECTRICAL CHARACTERISTICS

All parameters apply at $V_{DD} = 5V$, $T_A = -40°C$ to $+85°C$, $f_{SAMPLE} = 200$ ksp and $f_{CLK} = 16*f_{SAMPLE}$, unless otherwise noted.

3.1 Analog Inputs (CH0/CH1)

Analog inputs for channels 0 and 1 respectively. These channels can be programmed to be used as two independent channels in Single-Ended mode or as a single pseudo-differential input where one channel is IN+ and one channel is IN-. See Section 5.0 “Serial Communications” for information on programming the channel configuration.

3.2 Chip Select/Shutdown (CS/SHDN)

The CS/SHDN pin is used to initiate communication with the device when pulled low and will end a conversion and put the device in low power standby when pulled high. The CS/SHDN pin must be pulled high between conversions.

3.3 Serial Clock (CLK)

The SPI clock pin is used to initiate a conversion and to clock out each bit of the conversion as it takes place. See Section 6.2 “Maintaining Minimum Clock Speed” for constraints on clock speed.

3.4 Serial Data Input (DIN)

The SPI port serial data input pin is used to clock in input channel configuration data.

3.5 Serial Data Output (DOUT)

The SPI serial data output pin is used to shift out the results of the A/D conversion. Data will always change on the falling edge of each clock as the conversion takes place.
4.0 DEVICE OPERATION

The MCP3002 A/D converter employs a conventional SAR architecture. With this architecture, a sample is acquired on an internal sample/hold capacitor for 1.5 clock cycles starting on the second rising edge of the serial clock after the start bit has been received. Following this sample time, the input switch of the converter opens and the device uses the collected charge on the internal sample and hold capacitor to produce a serial 10-bit digital output code.

Conversion rates of 200 ksps are possible on the MCP3002. See Section 6.2 “Maintaining Minimum Clock Speed” for information on minimum clock rates.

Communication with the device is done using a 3-wire SPI-compatible interface.

4.1 Analog Inputs

The MCP3002 device offers the choice of using the analog input channels configured as two single-ended inputs that are referenced to VSS or a single pseudo-differential input. The configuration setup is done as part of the serial command before each conversion begins. When used in the pseudo-differential mode, CH0 and CH1 are programmed as the IN+ and IN- inputs as part of the command string transmitted to the device. The IN+ input can range from IN- to the reference voltage, VDD. The IN- input is limited to ±100 mV from the VSS rail. The IN- input can be used to cancel small signal common-mode noise which is present on both the IN+ and IN- inputs.

For the A/D converter to meet specification, the charge holding capacitor (CSAMPLE) must be given enough time to acquire a 10-bit accurate voltage level during the 1.5 clock cycle sampling period. The analog input model is shown in Figure 4-1.

In this diagram, it is shown that the source impedance (RS) adds to the internal sampling switch (RSS) impedance, directly affecting the time that is required to charge the capacitor, CSAMPLE. Consequently, larger source impedances increase the offset, gain, and integral linearity errors of the conversion.

Ideally, the impedance of the signal source should be near zero. This is achievable with an operational amplifier such as the MCP601 which has a closed loop output impedance of tens of ohms. The adverse affects of higher source impedances are shown in Figure 4-2.

When operating in the pseudo-differential mode, if the voltage level of IN+ is equal to or less than IN-, the resultant code will be 000h. If the voltage at IN+ is equal to or greater than \((VDD + (IN-) - 1\text{ LSB})\), then the output code will be 3FFh. Conversely, if IN- is more than 1 LSB above VSS, then the 3FFh code will not be seen unless the IN+ input level goes above VDD level. If the voltage at IN+ is equal to or greater than \((VDD + (IN-) - 1\text{ LSB})\), then the output code will be 3FFh.

4.2 Digital Output Code

The digital output code produced by an A/D Converter is a function of the input signal and the reference voltage. For the MCP3002, \(VDD\) is used as the reference voltage.

\[
\text{LSB Size} = \frac{V_{REF}}{1024}
\]

As the \(VDD\) level is reduced, the LSB size is reduced accordingly. The theoretical digital output code produced by the A/D Converter is shown below.

\[
\text{Digital Output Code} = \frac{1024 \times V_{IN}}{V_{DD}}
\]

Where:

- \(V_{IN}\) = analog input voltage
- \(V_{DD}\) = supply voltage
**FIGURE 4-1:** Analog Input Model.

5.0 SERIAL COMMUNICATIONS

5.1 Overview

Communication with the MCP3002 is done using a standard SPI-compatible serial interface. Initiating communication with the device is done by bringing the CS line low. See Figure 5-1. If the device was powered up with the CS pin low, it must be brought high and back low to initiate communication. The first clock received with CS low and DIN high will constitute a start bit. The SGL/DIFF bit and the ODD/SIGN bit follow the start bit and are used to select the input channel configuration. The SGL/DIFF is used to select Single-Ended or Pseudo-Differential mode. The ODD/SIGN bit selects which channel is used in Single-Ended mode, and is used to determine polarity in Pseudo-Differential mode. Following the ODD/SIGN bit, the MSBF bit is transmitted to and is used to enable the LSB first format for the device. If the MSBF bit is high, then the data will come from the device in MSB first format and any further clocks with CS low, will cause the device to output zeros. If the MSBF bit is low, then the device will output the converted word LSB first after the word has been transmitted in the MSB first format. Table 5-1 shows the configuration bits for the MCP3002. The device will begin to sample the analog input on the second rising edge of the clock, after the start bit has been received. The sample period will end on the falling edge of the third clock following the start bit.

On the falling edge of the clock for the MSBF bit, the device will output a low null bit. The next sequential 10 clocks will output the result of the conversion with MSB first as shown in Figure 5-1. Data is always output from the device on the falling edge of the clock. If all 10 data bits have been transmitted and the device continues to receive clocks while the CS is held low (and the MSBF bit is high), the device will output the conversion result LSB first as shown in Figure 5-2. If more clocks are provided to the device while CS is still low (after the LSB first data has been transmitted), the device will clock out zeros indefinitely.

If necessary, it is possible to bring CS low and clock in leading zeros on the DIN line before the start bit. This is often done when dealing with microcontroller-based SPI ports that must send 8 bits at a time. Refer to Section 6.1 “Using the MCP3002 with Microcontroller (MCU) SPI Ports” for more details on using the MCP3002 devices with hardware SPI ports.

If it is desired, the CS can be raised to end the conversion period at any time during the transmission. Faster conversion rates can be obtained by using this technique if not all the bits are captured before starting a new cycle. Some system designers use this method by capturing only the highest-order 8 bits and ‘throwing away’ the lower 2 bits.

FIGURE 5-1: Communication with the MCP3002 using MSB first format only.

* After completing the data transfer, if further clocks are applied with CS low, the A/D Converter will output zeros indefinitely. See Figure 5-2 for details on obtaining LSB first data.

** tDATA: during this time, the bias current and the comparator powers down while the reference input becomes a high-impedance node.

FIGURE 5-2: Communication with MCP3002 using LSB first format.

* After completing the data transfer, if further clocks are applied with CS low, the A/D Converter will output zeros indefinitely.

** tDATA: During this time, the bias circuit and the comparator powers down while the reference input becomes a high-impedance node, leaving the CLK running to clock out LSB first data or zeroes.
6.0 APPLICATIONS INFORMATION

6.1 Using the MCP3002 with Microcontroller (MCU) SPI Ports

With most microcontroller SPI ports, it is required to send groups of eight bits. It is also required that the microcontroller SPI port be configured to clock out data on the falling edge of clock and latch data in on the rising edge. Depending on how communication routines are used, it is very possible that the number of clocks required for communication will not be a multiple of eight. Therefore, it may be necessary for the MCU to send more clocks than are actually required. This is usually done by sending ‘leading zeros’ before the start bit, which are ignored by the device.

As an example, Figure 6-1 and Figure 6-2 show how the MCP3002 can be interfaced to a MCU with a hardware SPI port.

As shown in Figure 6-1, the first byte transmitted to the A/D Converter contains one leading zero before the start bit. Arranging the leading zero this way produces the output 10 bits to fall in positions easily manipulated by the MCU. When the first 8 bits are transmitted to the device, the MSB data bit is clocked out of the A/D converter on the falling edge of clock number 6. After the second eight clocks have been sent to the device, the receive register will contain the lowest-order eight bits of the conversion results. Easier manipulation of the converted data can be obtained by using this method.

**FIGURE 6-1:** SPI Communication with the MCP3002 using 8-bit segments (Mode 0,0: SCLK idles low).
6.2 Maintaining Minimum Clock Speed

When the MCP3002 initiates the sample period, charge is stored on the sample capacitor. When the sample period is complete, the device converts one bit for each clock that is received. It is important for the user to note that a slow clock rate will allow charge to bleed off the sample cap while the conversion is taking place. At 85°C (worst case condition), the part will maintain proper charge on the sample cap for 700 µs at $V_{DD} = 2.7\text{V}$ and 1.5 ms at $V_{DD} = 5\text{V}$. This means that at $V_{DD} = 2.7\text{V}$, the time it takes to transmit the 1.5 clocks for the sample period and the 10 clocks for the actual conversion must not exceed 700 µs. Failure to meet this criteria may induce linearity errors into the conversion outside the rated specifications.

6.3 Buffering/Filtering the Analog Inputs

If the signal source for the A/D Converter is not a low impedance source, it will have to be buffered or inaccurate conversion results may occur. It is also recommended that a filter be used to eliminate any signals that may be aliased back in to the conversion results. This is illustrated in Figure 6-3 below where an op amp is used to drive, filter, and gain the analog input of the MCP3002. This amplifier provides a low impedance output for the converter input and a low-pass filter, which eliminates unwanted high-frequency noise.

Low-pass (anti-aliasing) filters can be designed using Microchip's interactive FilterLab® software. FilterLab will calculate capacitor and resistors values, as well as, determine the number of poles that are required for the application. For more information on filtering signals, see the application note AN699 "Anti-Aliasing Analog Filters for Data Acquisition Systems."

![Typical Anti-Aliasing Filter Circuit (2 pole Active Filter).](image-url)
6.4 Layout Considerations

When laying out a printed circuit board for use with analog components, care should be taken to reduce noise wherever possible. A bypass capacitor should always be used with this device and should be placed as close as possible to the device pin. A bypass capacitor value of 1 µF is recommended.

Digital and analog traces should be separated as much as possible on the board and no traces should run underneath the device or the bypass capacitor. Extra precautions should be taken to keep traces with high-frequency signals (such as clock lines) as far as possible from analog traces.

Use of an analog ground plane is recommended in order to keep the ground potential the same for all devices on the board. Providing VDD connections to devices in a “star” configuration can also reduce noise by eliminating current return paths and associated errors. See Figure 6-4. For more information on layout tips when using A/D converters, refer to AN-688 “Layout Tips for 12-Bit A/D Converter Applications” (DS00688).

**FIGURE 6-4:** VDD traces arranged in a ‘Star’ configuration in order to reduce errors caused by current return paths.
7.0 PACKAGING INFORMATION

7.1 Package Marking Information

Legend:
- XX...X Customer-specific information
- Y Year code (last digit of calendar year)
- YY Year code (last 2 digits of calendar year)
- WW Week code (week of January 1 is week '01')
- NNN Alphanumeric traceability code
- \(\text{Pb-free JEDEC designator for Matte Tin (Sn)}\)
- * This package is Pb-free. The Pb-free JEDEC designator (\(\text{e3}\)) can be found on the outer packaging for this package.

Note: In the event the full Microchip part number cannot be marked on one line, it will be carried over to the next line, thus limiting the number of available characters for customer-specific information.
Package Marking Information (Continued)

8-Lead TSSOP (4.4 mm) Example

Legend:
- XX...X Customer-specific information
- Y Year code (last digit of calendar year)
- YY Year code (last 2 digits of calendar year)
- WW Week code (week of January 1 is week ‘01’)
- NNN Alphanumeric traceability code
- \(^3\) Pb-free JEDEC designator for Matte Tin (Sn)
- * This package is Pb-free. The Pb-free JEDEC designator \(^3\) can be found on the outer packaging for this package.

Note: In the event the full Microchip part number cannot be marked on one line, it will be carried over to the next line, thus limiting the number of available characters for customer-specific information.
8-Lead Plastic Micro Small Outline Package (MS) [MSOP]

Microchip Technology Drawing No. C04-2086A
APPENDIX A: REVISION HISTORY

Revision E (November 2011)
Updated Product Identification System
Corrected MSOP marking drawings.
Updated Package Specification Drawings with new additions.

Revision D (October 2008)
Updates to packaging outline drawings.

Revision C (January 2007)
Updates to packaging outline drawings.

Revision B (August 2001)
Undocumented changes.

Revision A (February 2000)
Initial release of this document.
# PRODUCT IDENTIFICATION SYSTEM

To order or obtain information, e.g., on pricing or delivery, refer to the factory or the listed sales office.

Temperature Range
- **I**: -40°C to +85°C (Industrial)

Package
- **MS**: Plastic Micro Small Outline (MSOP), 8-lead
- **P**: Plastic DIP (300 mil Body), 8-lead
- **SN**: Plastic SOIC (150 mil Body), 8-lead
- **ST**: Plastic TSSOP (4.4 mm), 8-lead

Examples:
- a) MCP3002-I/P: Industrial Temperature, 8LD PDIP package.
- b) MCP3002-I/SN: Industrial Temperature, 8LD SOIC package.
- c) MCP3002-I/ST: Industrial Temperature, 8LD TSSOP package.
- d) MCP3002-I/MS: Industrial Temperature, 8LD MSOP package.
Note the following details of the code protection feature on Microchip devices:

- Microchip products meet the specification contained in their particular Microchip Data Sheet.

- Microchip believes that its family of products is one of the most secure families of its kind on the market today, when used in the intended manner and under normal conditions.

- There are dishonest and possibly illegal methods used to breach the code protection feature. All of these methods, to our knowledge, require using the Microchip products in a manner outside the operating specifications contained in Microchip’s Data Sheets. Most likely, the person doing so is engaged in theft of intellectual property.

- Microchip is willing to work with the customer who is concerned about the integrity of their code.

- Neither Microchip nor any other semiconductor manufacturer can guarantee the security of their code. Code protection does not mean that we are guaranteeing the product as “unbreakable.”

Code protection is constantly evolving. We at Microchip are committed to continuously improving the code protection features of our products. Attempts to break Microchip’s code protection feature may be a violation of the Digital Millennium Copyright Act. If such acts allow unauthorized access to your software or other copyrighted work, you may have a right to sue for relief under that Act.

Information contained in this publication regarding device applications and the like is provided only for your convenience and may be superseded by updates. It is your responsibility to ensure that your application meets with your specifications. MICROCHIP MAKES NO REPRESENTATIONS OR WARRANTIES OF ANY KIND WHETHER EXPRESS OR IMPLIED, WRITTEN OR ORAL, STATUTORY OR OTHERWISE, RELATED TO THE INFORMATION, INCLUDING BUT NOT LIMITED TO ITS CONDITION, QUALITY, PERFORMANCE, MERCHANTABILITY OR FITNESS FOR PURPOSE. Microchip disclaims all liability arising from this information and its use. Use of Microchip devices in life support and/or safety applications is entirely at the buyer’s risk, and the buyer agrees to defend, indemnify and hold harmless Microchip from any and all damages, claims, suits, or expenses resulting from such use. No licenses are conveyed, implicitly or otherwise, under any Microchip intellectual property rights.
