Features

- Charge Pump in 5-Pin SOT-23 Package
- >95% Voltage Conversion Efficiency
- Voltage Inversion and/or Doubling
- Low 50 µA (TCM828) Quiescent Current
- Operates from +1.5V to +5.5V
- Up to 25 mA Output Current
- Only Two External Capacitors Required

Applications

- LCD Panel Bias
- Cellular Phones
- Pagers
- PDAs, Portable Dataloggers
- Battery-Powered Devices

Description

The TCM828/TCM829 devices are CMOS “charge-pump” voltage converters in ultra-small, 5-Pin SOT-23 packages. They invert and/or double an input voltage which can range from +1.5V to +5.5V. Conversion efficiency is typically >95%. Switching frequency is 12 kHz for the TCM828, and 35 kHz for the TCM829.

External component requirement is only two capacitors (3.3 µF nominal) for standard voltage inverter applications. With a few additional components, a positive doubler can also be built. All other circuitry, including control, oscillator and power MOSFETs, are integrated on-chip. Supply current is 50 µA (TCM828) and 115 µA (TCM829).

The TCM828 and TCM829 devices are available in a 5-Pin SOT-23 surface mount package.

4.0 DETAILED DESCRIPTION

The TCM828/TCM829 charge pump converters invert the voltage applied to the $V_{IN}$ pin. Conversion consists of a two phase operation (Figure 4-1). During the first phase, switches S2 and S4 are open, while S1 and S3 are closed. During this time, C1 charges to the voltage on $V_{IN}$ and load current is supplied from C2. During the second phase, S2 and S4 are closed, and S1 and S3 are open. This action connects C1 across C2, restoring charge to C2.

![Ideal Switched Capacitor Charge Pump](image)

FIGURE 4-1: Ideal Switched Capacitor Charge Pump.
5.0 APPLICATIONS INFORMATION

5.0.1 OUTPUT VOLTAGE CONSIDERATIONS

The TCM828/TCM829 devices perform voltage conversion, but do not provide regulation. The output voltage will droop in a linear manner with respect to load current. The value of this equivalent output resistance is approximately 25\( \Omega \) nominal at +25°C and \( V_{IN} = +5V \). \( V_{OUT} \) is approximately – 5V at light loads, and droops according to the equation below:

\[
V_{DROOP} = I_{OUT} \times R_{OUT} \\
V_{OUT} = -(V_{IN} - V_{DROOP})
\]

5.0.2 CHARGE PUMP EFFICIENCY

The overall power efficiency of the charge pump is affected by four factors:

1. Losses from power consumed by the internal oscillator, switch drive, etc. (which vary with input voltage, temperature and oscillator frequency).
2. \( I^2R \) losses due to the on-resistance of the MOSFET switches on-board the charge pump.
3. Charge pump capacitor losses due to effective series resistance (ESR).
4. Losses that occur during charge transfer (from the commutation capacitor to the output capacitor) when a voltage difference between the two capacitors exists.

Most of the conversion losses are due to factors 2, 3 and 4 above. These losses are shown in Equation 5-1.

\[
P_{LOSS(2,3,4)} = I_{OUT}^2 \times R_{OUT} \\
= I_{OUT}^2 \times \left[ \frac{1}{(V_{OSC})(C1)} + 8R_{SWITCH} + 4ESR_{C1} + ESR_{C2} \right]
\]

The 1/(\( f_{OSC} C1 \)) term in Equation 5-1 is the effective output resistance of an ideal switched capacitor circuit (Figures 5-1 and 5-2).

The losses in the circuit due to factor 4 above are also shown in Equation 5-2. The output voltage ripple is shown in Equation 5-3.

\[
P_{LOSS(4)} = \frac{(0.5)(C1)(V_{IN}^2 + V_{OUT}^2) + (0.5)(C2)V_{RIPPLE}^2}{V_{OUT}^2R_{RIPPLE}}
\]

\[
V_{RIPPLE} = I_{OUT} \times \frac{1}{(V_{OSC})(C2)} + 2(I_{OUT})(ESR_{C2})
\]
5.0.3 CAPACITOR SELECTION

In order to maintain the lowest output resistance and output ripple voltage, it is recommended that low ESR capacitors be used. Additionally, larger values of C1 will lower the output resistance and larger values of C2 will reduce output ripple. (See Equation 5-1).

Table 5-1 shows various values of C1 and the corresponding output resistance values @ +25°C. It assumes a 0.1Ω ESR<sub>C1</sub> and 2Ω<sub>RSW</sub>. Table 5-2 shows the output voltage ripple for various values of C2. The V<sub>RIPPLE</sub> values assume 10 mA output load current and 0.1Ω ESR<sub>C2</sub>.

5.0.4 INPUT SUPPLY BYPASSING

The V<sub>IN</sub> impedance should be capacitively bypassed to reduce AC impedance and minimize noise effects due to the switching internal to the device. The recommended capacitor depends on the configuration of the TCM828/TCM829 devices.

If the device is loaded from OUT to GND, it is recommended that a large value capacitor (at least equal to C1) be connected from the input to GND. If the device is loaded from IN to OUT, a small (0.1 µF) capacitor is sufficient.

5.0.5 VOLTAGE INVERTER

The most common application for charge pump devices is the inverter (Figure 5-3). This application uses two external capacitors – C1 and C2 (plus a power supply bypass capacitor, if necessary). The output is equal to V<sub>IN</sub> plus any voltage drops, due to loading. Refer to Table 5-1 and Table 5-1 for capacitor selection.

**FIGURE 5-3: Test Circuit.**

5.0.6 CASCADING DEVICES

Two or more TCM828/829 devices can be cascaded to increase output voltage (Table 5-4). If the output is lightly loaded, it will be close to (– 2 x VIN) but will droop at least by R<sub>OUT</sub> of the first device multiplied by the IQ of the second. It can be seen that the output resistance rises rapidly for multiple cascaded devices. For large negative voltage requirements see the TC682 or TCM680 data sheets.

**FIGURE 5-4:** Cascading TCM828 or TCM829 Devices to Increase Output Voltage.
5.0.7 PARALLELING DEVICES

To reduce the value of $R_{\text{OUT}}$, multiple TCM828/TCM829 devices can be connected in parallel (Figure 5-5). The output resistance will be reduced by a factor of $N$, where $N$ is the number of TCM828/TCM829 device. Each device will require its own pump capacitor ($C_1$), but all devices may share one reservoir capacitor ($C_2$). However, to preserve ripple performance, the value of $C_2$ should be scaled according to the number of paralleled TCM828/TCM829 devices.

![Figure 5-5: Paralleling TCM828 or TCM829 Devices to Reduce Output Resistance.](image)

5.0.8 VOLTAGE DOUBLER/INVERTER

Another common application of the TCM828/TCM829 devices is shown in Figure 5-6. This circuit performs two functions in combination. $C_1$ and $C_2$ form the standard inverter circuit described above. $C_3$ and $C_4$, plus the two diodes, form the voltage doubler circuit. $C_1$ and $C_3$ are the pump capacitors, while $C_2$ and $C_4$ are the reservoir capacitors. Because both sub-circuits rely on the same switches, if either output is loaded, both will drop toward GND. Make sure that the total current drawn from both the outputs does not total more than 40 mA.

![Figure 5-6: Combined Doubler and Inverter.](image)

5.0.9 DIODE PROTECTION FOR HEAVY LOADS

When heavy loads require the OUT pin to sink large currents, being delivered by a positive source, diode protection may be needed. The OUT pin should not be allowed to be pulled above ground. This is accomplished by connecting a Schottky diode (1N5817) as shown in Figure 5-7.

![Figure 5-7: High V– Load Current.](image)

5.0.10 LAYOUT CONSIDERATIONS

As with any switching power supply circuit, good layout practice is recommended. Mount components as close together as possible, to minimize stray inductance and capacitance. Also use a large ground plane to minimize noise leakage into other circuitry.

Note the following details of the code protection feature on Microchip devices:

- Microchip products meet the specification contained in their particular Microchip Data Sheet.
- Microchip believes that its family of products is one of the most secure families of its kind on the market today, when used in the intended manner and under normal conditions.
- There are dishonest and possibly illegal methods used to breach the code protection feature. All of these methods, to our knowledge, require using the Microchip products in a manner outside the operating specifications contained in Microchip’s Data Sheets. Most likely, the person doing so is engaged in theft of intellectual property.
- Microchip is willing to work with the customer who is concerned about the integrity of their code.
- Neither Microchip nor any other semiconductor manufacturer can guarantee the security of their code. Code protection does not mean that we are guaranteeing the product as “unbreakable.”

Code protection is constantly evolving. We at Microchip are committed to continuously improving the code protection features of our products. Attempts to break Microchip’s code protection feature may be a violation of the Digital Millennium Copyright Act. If such acts allow unauthorized access to your software or other copyrighted work, you may have a right to sue for relief under that Act.
