PWM Fan Speed Controllers With Minimum Fan Speed, Fan Restart and FanSense™ Technology for Fault Detection

Features

• Temperature-Proportional Fan Speed for Acoustic Noise Reduction and Longer Fan Life
• Efficient PWM Fan Drive
• 3.0V to 5.5V Supply Range:
  - Fan Voltage Independent of TC642B/TC647B Supply Voltage
  - Supports any Fan Voltage
• FanSense™ Fault Detection Circuit Protects Against Fan Failure and Aids System Testing
• Shutdown Mode for “Green” Systems
• Supports Low Cost NTC/PTC Thermistors
• Over-Temperature Indication (TC642B only)
• Fan Auto-Restart
• Space-Saving 8-Pin MSOP Package

Applications

• Personal Computers & Servers
• LCD Projectors
• Datacom & Telecom Equipment
• Fan Trays
• File Servers
• General Purpose Fan Speed Control

Description

The TC642B/TC647B devices are new versions of the existing TC642/TC647 fan speed controllers. These devices are switch mode, fan speed controllers that incorporate a new fan auto-restart function. Temperature-proportional speed control is accomplished using pulse width modulation. A thermistor (or other voltage output temperature sensor) connected to the \( V_{IN} \) input supplies the required control voltage of 1.20V to 2.60V (typical) for 0% to 100% PWM duty cycle. Minimum fan speed is set by a simple resistor divider on the \( V_{MIN} \) input. An integrated Start-Up Timer ensures reliable motor start-up at turn-on, coming out of shutdown mode or following a transient fault. A logic-low applied to \( V_{MIN} \) (pin 3) causes fan shutdown.

The TC642B and TC647B also feature Microchip Technology’s proprietary FanSense™ technology for increasing system reliability. In normal fan operation, a pulse train is present at SENSE (pin 5). A missing-pulse detector monitors this pin during fan operation. A stalled, open or unconnected fan causes the TC642B/TC647B device to turn the \( V_{OUT} \) output on full (100% duty cycle). If the fault persists (a fan current pulse is not detected within a 32/7 period), the FAULT output goes low. Even with the FAULT output low, the \( V_{OUT} \) output is on full during the fan fault condition in order to attempt to restart the fan. FAULT is also asserted if the PWM reaches 100% duty cycle (TC642B only), indicating that maximum cooling capability has been reached and a possible overheating condition exists.

The TC642B and TC647B devices are available in 8-pin plastic MSOP, SOIC and PDIP packages. The specified temperature range of these devices is -40 to +85°C.
Functional Block Diagram

Note: The \( V_{\text{OTF}} \) comparator is for the TC642B device only.

</table>

3.1 Analog Input (V_IN)

The thermistor network (or other temperature sensor) connects to V_IN. A voltage range of 1.20V to 2.60V (typical) on this pin drives an active duty cycle of 0% to 100% on the V_OUT pin.

3.2 Analog Output (C_F)

C_F is the positive terminal for the PWM ramp generator timing capacitor. The recommended value for the C_F capacitor is 1.0 µF for 30 Hz PWM operation.

3.3 Analog Input (V_MIN)

An external resistor divider connected to V_MIN sets the minimum fan speed by fixing the minimum PWM duty cycle (1.20V to 2.60V = 0% to 100%, typical). The TC642B and TC647B devices enter shutdown mode when 0 ≤ V_MIN ≤ V_SHDN. During shutdown, the FAULT output is inactive and supply current falls to 30 µA (typical).

3.4 Analog Input (SENSE)

Pulses are detected at SENSE as fan rotation chops the current through a sense resistor. The absence of pulses indicates a fan fault condition.

3.5 Digital (Open-Drain) Output (FAULT)

The FAULT line goes low to indicate a fault condition. When FAULT goes low due to a fan fault, the output will remain low until the fan fault condition has been removed (16 pulses have been detected at the SENSE pin in a 32/f period). For the TC642B device, the FAULT output will also be asserted when the V_IN voltage reaches the V_OTF threshold of 2.62V (typical). This gives an over-temperature/100% fan speed indication.

3.6 Digital Output (V_OUT)

V_OUT is an active-high complimentary output and drives the base of an external NPN transistor (via an appropriate base resistor) or the gate of an N-channel MOSFET. This output has asymmetrical drive. During a fan fault condition, the V_OUT output is continuously on.

3.7 Power Supply Input (V_DD)

The V_DD pin with respect to GND provides power to the device. This bias supply voltage may be independent of the fan power supply.
4.0 DEVICE OPERATION

The TC642B/TC647B devices are a family of temperature proportional, PWM mode, fan speed controllers. Features of the family include minimum fan speed, fan auto-shutdown mode, fan auto-restart, remote shutdown, over-temperature indication and fan fault detection.

The TC642B/TC647B family is slightly different from the original TC64X family, which includes the TC642, TC646, TC647, TC648 and TC649 devices. Changes have been made to adjust the operation of the device during a fan fault condition.

The key change to the TC64XB family of devices (TC642B, TC647B, TC646B, TC648B, TC649B) is that the FAULT and V\text{OUT} outputs no longer "latch" to a state during a fan fault condition. The TC64XB family will continue to monitor the operation of the fan so that when the fan returns to normal operation, the fan speed controller will also return to normal operation (PWM mode). The operation and features of these devices are discussed in the following sections.

4.1 Fan Speed Control Methods

The speed of a DC brushless fan is proportional to the voltage across it. This relationship will vary from fan to fan and should be characterized on an individual basis. The speed versus applied voltage relationship can then be used to set up the fan speed control algorithm.

There are two main methods for fan speed control. The first is pulse width modulation (PWM) and the second is linear. Using either method, the total system power requirement to run the fan is equal. The difference between the two methods is where the power is consumed.

The following example compares the two methods for a 12V, 120 mA fan running at 50% speed. With 6V applied across the fan, the fan draws an average current of 68 mA.

Using a linear control method, there is 6V across the fan and 6V across the drive element. With 6V and 68 mA, the drive element is dissipating 410 mW of power.

Using the PWM approach, the fan voltage is modulated at a 50% duty cycle with most of the 12V being dropped across the fan. With 50% duty cycle, the fan draws an RMS current of 110 mA and an average current of 72 mA. Using a MOSFET with a 1 \Omega R_{DS(on)} (a fairly typical value for this low current), the power dissipation in the drive element would be: 12 mW (I_{rms}^2 \times R_{DS(on)}).

Using a standard 2N2222A NPN transistor (assuming a V\text{ce-sat} of 0.8V), the power dissipation would be 58 mW (I_{avg} \times V\text{ce-sat}).

The PWM approach to fan speed control results in much less power dissipation in the drive element, allowing smaller devices to be used while not requiring special heatsinking to remove the power being dissipated in the package.

The other advantage of the PWM approach is that the voltage being applied to the fan is always near 12V. This eliminates any concern about not supplying a high enough voltage to run the internal fan components, which is very relevant in linear fan speed control.

4.2 PWM Fan Speed Control

The TC642B and TC647B devices implement PWM fan speed control by varying the duty cycle of a fixed frequency pulse train. The duty cycle of a waveform is the on time divided by the total period of the pulse. For example, a 100 Hz waveform (10 ms) with an on time of 5.0 ms has a duty cycle of 50% (5.0 ms / 10.0 ms). This example is illustrated in Figure 4-1.

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{PWM_Duty_Cycle.png}
\caption{Duty Cycle of a PWM Waveform.}
\end{figure}

The TC642B and TC647B generate a pulse train with a typical frequency of 30 Hz (C_F = 1 \mu F). The duty cycle can be varied from 0% to 100%. The pulse train generated by the TC642B/TC647B device drives the gate of an external N-channel MOSFET or the base of an NPN transistor (shown in Figure 4-2). See Section 5.5, “Output Drive Device Selection”, for more information.

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{PWM_Fan_Drive.png}
\caption{PWM Fan Drive.}
\end{figure}
By modulating the voltage applied to the gate of the MOSFET (QDRIVE), the voltage that is applied to the fan is also modulated. When the VOUT pulse is high, the gate of the MOSFET is turned on, pulling the voltage at the drain of QDRIVE to zero volts. This places the full 12V across the fan for the t_on period of the pulse. When the duty cycle of the drive pulse is 100% (full on, t_on = t), the fan will run at full speed. As the duty cycle is decreased (pulse on time “t_on” is lowered), the fan will slow down proportionally. With the TC642B and TC647B devices, the duty cycle is controlled by either the VIN or VMIN input, with the higher voltage setting the duty cycle. This is described in more detail in Section 5.5, “Output Drive Device Selection”.

4.3 Fan Start-up

Often overlooked in fan speed control is the actual start-up control period. When starting a fan from a non-operating condition (fan speed is zero revolutions per minute (RPM)), the desired PWM duty cycle or average fan voltage can not be applied immediately. Since the fan is at a rest position, the fan's inertia must be overcome to get it started. The best way to accomplish this is to apply the full rated voltage to the fan for a minimum of one second. This will ensure that in all operating environments, the fan will start and operate properly. An example of the start-up timing is shown in Figure 1-1.

A key feature of the TC642B/TC647B device is the start-up timer. When power is first applied to the device, (when the device is brought out of the shutdown mode of operation) the VOUT output will go to a high state for 32 PWM cycles (one second for CF = 1 µF). This will drive the fan to full speed for this time-frame.

During the start-up period, the SENSE pin is being monitored for fan pulses. If pulses are detected during this period, the fan speed controller will then move to PWM operation (see Section 4.5, “Minimum Fan Speed”, for more details on operation when coming out of start-up). If pulses are not detected during the start-up period, the start-up timer is activated again. If pulses are not detected at the SENSE pin during this additional start-up period, the FAULT output will go low to indicate that a fan fault condition has occurred. See Section 4.7, “FAULT Output”, for more details.

4.4 PWM Frequency & Duty Cycle Control (CF & VIN Pins)

The frequency of the PWM pulse train is controlled by the CF pin. By attaching a capacitor to the CF pin, the frequency of the PWM pulse train can be set to the desired value. The typical PWM frequency for a 1.0 µF capacitor is 30 Hz. The frequency can be adjusted by raising or lowering the value of the capacitor. The CF pin functions as a ramp generator. The voltage at this pin will ramp from 1.20V to 2.60V (typically) as a sawtooth waveform. An example of this is shown in Figure 4-3.

The duty cycle of the PWM output is controlled by the voltage at the VIN input pin (or the VMIN voltage, whichever is greater). The duty cycle of the PWM output is produced by comparing the voltage at the VIN pin to the voltage ramp at the CF pin. When the voltage at the VIN pin is 1.20V, the duty cycle will be 0%. When the voltage at the VIN pin is 2.60V, the PWM duty cycle will be 100% (these are both typical values). The VIN to PWM duty cycle relationship is shown in Figure 4-4.

The lower value of 1.20V is referred to as VCMIN and the 2.60V threshold is referred to as VCMAX. A calculation for duty cycle is shown in the equation below. The voltage range between VCMIN and VCMAX is characterized as VCSpan and has a typical value of 1.4V with minimum and maximum values of 1.3V and 1.5V, respectively.

\[
\text{Duty Cycle} (%) = \frac{(V_{IN} - V_{C}\text{MIN}) \times 100}{V_{C}\text{MAX} - V_{C}\text{MIN}}
\]
FIGURE 4-4: VIN voltage vs. PWM duty cycle (Typical).

The PWM duty cycle is also controlled by the V_MIN pin. See Section 4.5, "Minimum Speed (V_MIN Pin)", for more details on this function.

4.5 Minimum Speed (V_MIN Pin)

For the TC642B and TC647B devices, pin 3 is the V_MIN pin. This pin is used for setting the minimum fan speed threshold.

The minimum fan speed function provides a way to set a threshold for a minimum duty cycle on the V_OUT output. This in turn produces a minimum fan speed for the user. The voltage range for the V_MIN pin is the same as that for the VIN pin (1.20V to 2.60V). The voltage at the V_MIN pin is set in this range so that as the voltage at the VIN pin decreases below the V_MIN voltage, the output duty cycle will be controlled by the V_MIN voltage. The following equation can be used to determine the necessary voltage at V_MIN for a desired minimum duty cycle on V_OUT:

EQUATION V_MIN VOLTAGE

\[ V_{\text{MIN}} (V) = \left( \frac{DC \times 1.4}{100} \right) + 1.20 \]

DC = Desired Duty Cycle

Example: If a minimum duty cycle of 40% is desired, the V_MIN voltage should be set to:

EXAMPLE 4-1:

\[ V_{\text{MIN}} (V) = \left( \frac{40 \times 1.4}{100} \right) + 1.20 \]

\[ V_{\text{MIN}} = 1.76V \]

If the voltage at the VIN pin falls below 1.76V, the duty cycle of the V_OUT output will not decrease below the 40% value that is now set by the voltage at the V_MIN pin. In this manner, the fan will continue to operate at 40% speed even when the temperature (voltage at VIN) continues to decrease.

For the TC642B and TC647B devices, the V_MIN pin is also used as the shutdown pin. The V_SHDN and V_REL threshold voltages are characterized in the “Electrical Characteristics” table of Section 1.0. If the V_MIN pin voltage is pulled below the V_SHDN threshold, the device will shut down (V_OUT output goes to a low state, the FAULT pin is inactive). If the voltage on the V_MIN pin then rises above the release threshold (V_REL), the device will go through a Power-Up sequence. The Power-Up sequence is shown later in Figure 4-9.

4.6 V_OUT Output (PWM Output)

The V_OUT output is a digital output designed for driving the base of a transistor or the gate of a MOSFET. The V_OUT output is designed to be able to quickly raise the base current or the gate voltage of the external drive device to its final value.

When the device is in shutdown mode, the V_OUT output is actively held low. The output can be varied from 0% duty cycle (full off) to 100% duty cycle (full on). As previously discussed, the duty cycle of the V_OUT output is controlled via the VIN input voltage along with the V_MIN voltage.

A base current-limiting resistor is required when using a transistor as the external drive device in order to limit the amount of drive current that is drawn from the V_OUT output.

The V_OUT output can be directly connected to the gate of an external MOSFET. One concern when doing this, though, is that the fast turn-off time of the fan drive MOSFET can cause a problem. The fan motor looks like an inductor. When the MOSFET is turned off quickly, the current in the fan wants to continue to flow in the same direction. This causes the voltage at the drain of the MOSFET to rise. If there aren’t any clamp diodes internal to the fan, this voltage can rise above the drain-to-source voltage rating of the MOSFET. For this reason, an external clamp diode is suggested. This is shown in Figure 4-5.
FIGURE 4-5: Clamp Diode for Fan.

4.7 FAULT Output

The FAULT output is an open-drain, active-low output. For the TC642B and TC647B devices, the FAULT output indicates when a fault condition has occurred. For the TC642B device, the FAULT output also indicates when an over-temperature (OTF) condition has occurred.

For the TC642B device, an over-temperature condition is indicated (FAULT output is pulled low) when the V IN input reaches the V OTF threshold voltage (the V OTF threshold voltage is typically 20 mV higher than the V CMAX threshold and has 80 mV of hysteresis). This indicates that maximum cooling capacity has been reached (the fan is at full speed) and that an overheating situation can occur. When the voltage at the V IN input falls below the V OTF threshold voltage by the hysteresis value (V OTF-HYS), the FAULT output returns to the high-state (a pull-up resistor is needed on the FAULT output).

A fan fault condition is indicated when fan current pulses are no longer detected at the SENSE pin. Pulses at the SENSE pin indicate that the fan is spinning and conducting current.

If pulses are not detected at the SENSE pin for 32 PWM cycles, the 3-cycle diagnostic timer is fired. This means that the V OUT output is high for 3 PWM cycles. If pulses are detected in this 3-cycle period, then normal PWM operation is resumed and no fault condition is indicated. If no pulses are detected in the 3-cycle period, the start-up timer is activated and the V OUT output is driven high for 32 PWM cycles. If pulses are detected during this time frame, normal PWM operation is resumed. If no pulses are detected during this time frame, a fan fault condition exists and the FAULT output is pulled low.

During a fan fault condition, the FAULT output will remain low until the fault condition has been removed. During this time, the V OUT output is driven high continuously to attempt to restart the fan, and the SENSE pin is monitored for fan pulses. If a minimum of 16 pulses are detected at the SENSE input over a 32 cycle time period (one second for C F = 1.0 µF), the fan fault condition no longer exists. The FAULT output is then released and the V OUT output returns to normal PWM operation, as dictated by the V IN and V MIN inputs.

If the V MIN voltage is pulled below the V SHDN level during a fan fault condition, the FAULT output will be released and the V OUT output will be shutdown (V OUT = 0V). If the V MIN voltage then increases above the V REL threshold, the device will go through the normal start-up routine.

If, during a fan fault condition, the voltage at the V IN pin drops below the V MIN voltage level, the TC642B/TC647B device will continue to hold the FAULT line low and drive the V OUT output to 100% duty cycle. If the fan fault condition is then removed, the FAULT output will be released and the V OUT output will be driven to the duty cycle that is being commanded by the V MIN input.

The sink current capability of the FAULT output is listed in the “Electrical Characteristics” table of Section 1.0.

4.8 Sensing Fan Operation (SENSE)

The SENSE input is an analog input used to monitor the fan’s operation. It does this by sensing fan current pulses, which represent fan rotation. When a fan rotates, commutation of the fan current occurs as the fan poles pass the armatures of the motor. The commutation of the fan current makes the current waveshape appear as pulses. There are two typical current waveforms of brushless DC fan motors. These are shown in Figures 4-6 and 4-7.

FIGURE 4-6: Fan Current With DC Offset And Positive Commutation Current.
TC642B/TC647B

The SENSE pin senses positive voltage pulses that have an amplitude of 70 mV (typical value). When a pulse is detected, the missing pulse detector timer is reset. As previously stated, if the missing pulse detector timer reaches the time for 32 cycles, the loop for diagnosing a fan fault is engaged (diagnostic timer, then the start-up timer).

Both of the fan current waveshapes that are shown in Figures 4-6 and 4-7 can be sensed with the sensing scheme shown in Figure 4-8.

The behavioral algorithm for the TC642B/TC647B devices is shown in Figure 4-9.

The behavioral algorithm shows the step-by-step decision-making process for the fan speed controller operation. The TC642B and TC647B devices are very similar with one exception: the TC647B device does not implement the over-temperature portion of the algorithm.
**FIGURE 4-9:** TC642B/TC647B Behavioral Algorithm.
5.0 APPLICATIONS INFORMATION

5.1 Setting the PWM Frequency

The PWM frequency of the VOUT output is set by the capacitor value attached to the CF pin. The PWM frequency will be 30 Hz (typical) for a 1 µF capacitor. The relationship between frequency and capacitor value is linear, making alternate frequency selections easy.

As stated in previous sections, the PWM frequency should be kept in the range of 15 Hz to 35 Hz. This will eliminate the possibility of having audible frequencies when varying the duty cycle of the fan drive.

A very important factor to consider when selecting the PWM frequency for the TC642B/TC647B devices is the RPM rating of the selected fan and the minimum duty cycle that the fan will be operating at. For fans that have a full speed rating of 3000 RPM or less, it is desirable to use a lower PWM frequency. A lower PWM frequency allows for a longer time period to monitor the fan current pulses. The goal is to be able to monitor at least two fan current pulses during the on time of the VOUT output.

Example: The system design requirement is to operate the fan at 50% duty cycle when ambient temperatures are below 20°C. The fan full speed RPM rating is 3000 RPM and has four current pulses per rotation. At 50% duty cycle, the fan will be operating at approximately 1500 RPM.

EQUATION

\[
\text{Time for one revolution (msec.)} = \frac{60 \times 1000}{1500} = 40
\]

If one fan revolution occurs in 40 msec, each fan pulse occurs 10 msec apart. In order to detect two fan current pulses, the on time of the VOUT pulse must be at least 20 msec. With the duty cycle at 50%, the total period of one cycle must be at least 40 msec, which makes the PWM frequency 25 Hz. For this example, a PWM frequency of 20 Hz is recommended. This would define a CF capacitor value of 1.5 µF.

5.2 Temperature Sensor Design

As discussed in previous sections, the VIN analog input has a range of 1.20V to 2.60V (typical), which represents a duty cycle range on the VOUT output of 0% to 100%, respectively. The VIN voltages can be thought of as representing temperatures. The 1.20V level is the low temperature at which the system requires very little cooling. The 2.60V level is the high temperature, for which the system needs maximum cooling capability (100% fan speed).

One of the simplest ways of sensing temperature over a given range is to use a thermistor. By using an NTC thermistor, as shown in Figure 5-1, a temperature variant voltage can be created.

**FIGURE 5-1:** Temperature Sensing Circuit.

Figure 5-1 represents a temperature-dependent voltage divider circuit. RT is a conventional NTC thermistor, while R1 and R2 are standard resistors. R1 and RT form a parallel resistor combination that will be referred to as RTEMP (\(R_{TEMP} = R_1 + R_T / R_1 + R_T\)). As the temperature increases, the value of RT decreases and the value of RTEMP will decrease with it. Accordingly, the voltage at VIN increases as temperature increases, giving the desired relationship for the VIN input. R1 helps to linearize the response of the sense network and aids in obtaining the proper VIN voltages over the desired temperature range. An example of this is shown in Figure 5-2.

If less current draw from VDD is desired, a larger value thermistor should be chosen. The voltage at the VIN pin can also be generated by a voltage output temperature sensor device. The key is to get the desired VIN voltage to system (or component) temperature relationship.

The following equations apply to the circuit in Figure 5-1.

**EQUATION**

\[
V(T1) = \frac{V_{DD} \times R_2}{R_{TEMP}(T1) + R_2}
\]

\[
V(T2) = \frac{V_{DD} \times R_2}{R_{TEMP}(T2) + R_2}
\]

In order to solve for the values of R1 and R2, the values for VIN, and the temperatures at which they are to occur, need to be selected. The variables T1 and T2 represent the selected temperatures. The value of the thermistor at these two temperatures can be found in the thermistor data sheet. With the values for the thermistor and the values for VIN, there are now two equations from which the values for R1 and R2 can be found.
Example: The following design goals are desired:

- Duty Cycle = 50% (V_IN = 1.90 V) with Temperature (T1) = 30°C
- Duty Cycle = 100% (V_IN = 2.60 V) with Temperature (T2) = 60°C

Using a 100 kΩ thermistor (25°C value), look up the thermistor values at the desired temperatures:

- R_T (T1) = 79428Ω @ 30°C
- R_T (T2) = 22593Ω @ 60°C

Substituting these numbers into the given equations produces the following numbers for R_1 and R_2.

- R_1 = 34.8 kΩ
- R_2 = 14.7 kΩ

5.4 FanSense Network (RSENSE and CSENSE)

The FanSense Network (comprised of RSENSE and CSENSE) allows the TC642B and TC647B devices to detect commutation of the fan motor. RSENSE converts the fan current into a voltage. CSENSE AC couples this voltage signal to the SENSE pin. The goal of the sense network is to provide a voltage pulse to the SENSE pin that has a minimum amplitude of 90 mV. This will ensure that the current pulse caused by the fan commutation is recognized by the TC642B/TC647B device.

A 0.1 µF ceramic capacitor is recommended for CSENSE. Smaller values will require that larger sense resistors be used. Using a 0.1 µF capacitor results in reasonable values for RSENSE. Figure 5-3 illustrates a typical SENSE network.

5.3 Thermistor Selection

As with any component, there are a number of sources for thermistors. A listing of companies that manufacture thermistors can be found at www.temperatures.com/thermivendors.html. This website lists over forty suppliers of thermistor products. A brief list is shown here.

- Thermometrics®
- Ametherm®
- U.S. Sensors™
- Advanced Thermal Products™
- Quality Thermistor™
- Sensor Scientific™
- Vishay®
- muRata®

Table 5-1 shows values of RSENSE according to the nominal operating current of the fan. The fan currents are average values. If the fan current falls between two of the values listed, use the higher resistor value.

The values listed in Table 5-1 are for fans that have the fan current waveshape shown in Figure 4-7. With this waveshape, the average fan current is closer to the peak value, which requires the resistor value to be higher. When using a fan that has the fan current waveshape shown in Figure 4-6, the resistor value can often be decreased since the current peaks are higher than the average and it is the AC portion of the voltage that gets coupled to the SENSE pin.

The key point when selecting an $R_{SENSE}$ value is to try to minimize the value in order to minimize the power dissipation in the resistor. In order to do this, it is critical to know the waveshape of the fan current and not just the average value.

Figure 5-4 shows some typical waveforms for the fan current and the voltage at the SENSE pin.

Another important factor to consider when selecting the $R_{SENSE}$ value is the fan current value during a locked rotor condition. When a fan is in a locked rotor condition (fan blades are stopped even though power is being applied to the fan), the fan current can increase dramatically, often 2.5 to 3.0 times the normal operating fan current. This will affect the power rating of the $R_{SENSE}$ resistor selected.

When selecting the fan for the application, the current draw of the fan during a locked rotor condition should be considered, especially if multiple fans are being used in the application.

There are two main types of fan designs when looking at fan current draw during a locked rotor condition.

The first is a fan that will simply draw high DC currents when put into a locked rotor condition. Many older fans were designed this way. An example of this is a fan that draws an average current of 100 mA during normal operation. In a locked rotor condition, this fan will draw 250 mA of average current. For this design, the $R_{SENSE}$ power rating must be sized to handle the 250 mA condition. The fan bias supply must also take this into account.

The second style design, which represents many of the newer fan designs today, acts to limit the current in a locked rotor condition by going into a pulse mode of operation. An example of the fan current waveshape for this style fan is shown in Figure 5-5. The fan represented in Figure 5-5 is a Panasonic®, 12V, 220 mA fan. During the on time of the waveform, the fan current is peaking up to 550 mA. Due to the pulse mode operation, however, the actual RMS current of the fan is very near the 220 mA rating. Because of this, the power rating for the $R_{SENSE}$ resistor does not have to be oversized for this application.
FIGURE 5-5: Fan Current During a Locked Rotor Condition.

5.5 Output Drive Device Selection

The TC642B/TC647B is designed to drive an external NPN transistor or N-channel MOSFET as the fan speed modulating element. These two arrangements are shown in Figure 5-7. For lower current fans, NPN transistors are a very economical choice for the fan drive device. It is recommended that, for higher current fans (300 mA and above), MOSFETs be used as the fan drive device. Table 5-2 provides some possible part numbers for use as the fan drive element.

When using a NPN transistor as the fan drive element, a base current-limiting resistor must be used, as is shown in Figure 5-7.

When using MOSFETs as the fan drive element, it is very easy to turn the MOSFETs on and off at very high rates. Because the gate capacitances of these small MOSFETs are very low, the TC642B/TC647B can charge and discharge them very quickly, leading to very fast edges. Of key concern is the turn-off edge of the MOSFET. Since the fan motor winding is essentially an inductor, once the MOSFET is turned off, the current that was flowing through the motor wants to continue to flow. If the fan does not have internal clamp diodes around the windings of the motor, there is no path for this current to flow through, and the voltage at the drain of the MOSFET may rise until the drain-to-source rating of the MOSFET is exceeded. This will most likely cause the MOSFET to go into avalanche mode. Since there is very little energy in this occurrence, it will probably not fail the device, but it would be a long-term reliability issue.

The following is recommended:
- Ask how the fan is designed. If the fan has clamp diodes internally, this problem will not be seen. If the fan does not have internal clamp diodes, it is a good idea to put one externally (Figure 5-6). Putting a resistor between $V_{OUT}$ and the gate of the MOSFET will also help slow down the turn-off and limit this condition.

FIGURE 5-5: Fan Current During a Locked Rotor Condition.

FIGURE 5-6: Clamp Diode For Fan Turn-Off.
5.6 Bias Supply Bypassing and Noise Filtering

The bias supply (V_{DD}) for the TC642B/TC647B devices should be bypassed with a 1.0 µF ceramic capacitor. This capacitor will help supply the peak currents that are required to drive the base/gate of the external fan drive devices.

As the V_{IN} pin controls the duty cycle in a linear fashion, any noise on this pin can cause duty-cycle jittering. For this reason, the V_{IN} pin should be bypassed with a 0.01 µF capacitor.

In order to keep fan noise off of the TC642B/TC647B device ground, individual ground returns for the TC642B/TC647B and the low side of the fan current sense resistor should be used.

5.7 Design Example/Typical Application

The system has been designed with the following components and criteria.

System inlet air ambient temperature ranges from 0°C to 50°C. At 20°C and below, it is desired to have the system cooling stay at a constant level. At 20°C, the fan should be run at 40% of its full fan speed. Full fan speed should be reached when the ambient air is 40°C.

The system has a surface mount, NTC-style thermistor in a 1206 package. The thermistor is mounted on a daughtercard, which is directly in the inlet air stream. The thermistor is a NTC, 100 kΩ @ 25°C, Thermometrics® part number NHQ104B425R5. The given Beta for the thermistor is 4250. The system bias voltage to run the fan controller is 5V and the fan voltage is 12V.
The fan used in the system is a Panasonic®, Panaflo®-series fan, model number FBA06T12H.

A fault indication is desired when the fan is in a locked rotor condition. This signal is used to indicate to the system that cooling is not available and a warning should be issued to the user. No fault indication from the fan controller is necessary for an over-temperature condition, as this is being reported elsewhere.

**Step 1: Gathering Information.**

The first step in the design process is to gather the needed data on the fan and thermistor. For the fan, it is also a good idea to look at the fan current waveform, as indicated earlier in the data sheet.

**Fan Information:** Panasonic number: FBA06T12H
- Voltage = 12V
- Current = 145 mA (number from data sheet)

**FIGURE 5-8:** FBA06T12H fan current waveform.

From the waveform in Figure 5-8, the fan current has an average value of 120 mA, with peaks up to 150 mA. This information will help in the selection of the RSENSE and CSENSE values later on. Also of interest for the RSENSE selection value is what the fan current does in a locked-rotor condition.

**FIGURE 5-9:** FBA06T12H Locked rotor fan current.

From Figure 5-9 it is seen that in a locked-rotor fault condition, the fan goes into a pulsed current mode of operation. During this mode, when the fan is conducting current, the peak current value is 360 mA for periods of 200 msec. This is significantly higher than the average full fan speed current shown in Figure 5-8. However, because of the pulse mode, the average fan current in a locked-rotor condition is lower and was measured at 68 mA. The RMS current during this mode, which is necessary for current sense resistor (RSENSE) value selection, was measured at 154 mA. This is slightly higher than the RMS value during full fan speed operation.

**Thermistor Information:** Thermometrics part number: NHQ104B425R5
- Resistance Value: 100 kΩ @ 25ºC
- Beta Value (β): 4250

From this information, the thermistor values at 20ºC and 40ºC must be found. This information is needed in order to select the proper resistor values for R1 and R2 (see Figure 5-13), which sets the VIN voltage.

The equation for determining the thermistor values is shown below:

\[
R_T = R_{TO} \exp \left[ \frac{\beta (T_0 - T)}{T \cdot T_0} \right]
\]

\(R_{TO}\) is the thermistor value at 25ºC. \(T_0\) is 298.15 and \(T\) is the temperature of interest. All temperatures are given in degrees kelvin.

Using this equation, the values for the thermistor are found to be:
- \(R_T (20ºC) = 127,462\Omega\)
- \(R_T (40ºC) = 50,520\Omega\)
Step 2: Selecting the Fan Controller.

The requirements for the fan controller are that it have minimum speed capability at 20°C and also indicate a fan fault condition. No over-temperature indication is necessary. Based on these specifications, the proper selection is the TC647B device.

Step 3: Setting the PWM Frequency.

The fan is rated at 4200 RPM with a 12V input. Since the goal is to run to a 40% duty cycle (roughly 40% fan speed), which equates to approximately 1700 RPM, we can assume one full fan revolution occurs every 35 msec. The fan being used is a four-pole fan that gives four current pulses per revolution. Knowing this and viewing test results at 40% duty cycle, two fan current pulses were always seen during the PWM on time with a PWM frequency of 30 Hz. For this reason, the $C_F$ value is selected to be 1.0 $\mu$F.

Step 4: Setting the $V_{IN}$ Voltage.

From the design criteria, the desired duty cycle at 20°C is 40%, while full fan speed should be reached at 40°C. Based on a $V_{IN}$ voltage range of 1.20V to 2.60V, which represents 0% to 100% duty cycle, the 40% duty cycle voltage can be found using the following equation:

$$V_{IN} = (DC * 1.4V) + 1.20V$$

$DC =$ Desired Duty Cycle

Using the above equation, the $V_{IN}$ values are calculated to be:

- $V_{IN}$ (40%) = 1.76V
- $V_{IN}$ (100%) = 2.60V

Using these values in combination with the thermistor resistance values calculated earlier, the $R_1$ and $R_2$ resistor values can now be calculated using the following equation:

$$V(T1) = \frac{V_{DD} \times R_2}{R_{TEMP}(T1) + R_2}$$

$$V(T2) = \frac{V_{DD} \times R_2}{R_{TEMP}(T2) + R_2}$$

$R_{TEMP}$ is the parallel combination of $R_1$ and the thermistor. $V(T1)$ represents the $V_{IN}$ voltage at 20°C and $V(T2)$ represents the $V_{IN}$ voltage at 40°C. Solving the equations simultaneously yields the following values ($V_{DD} = 5V$):

- $R_1 = 238,455 \Omega$
- $R_2 = 45,161 \Omega$

Using standard 1% resistor values, the selected $R_1$ and $R_2$ values are:

- $R_1 = 237 k\Omega$
- $R_2 = 45.3 k\Omega$

A graph of the $V_{IN}$ voltage, thermistor resistance and $R_{TEMP}$ resistance versus temperature for this configuration is shown in Figure 5-10.

Step 5: Setting the Minimum Speed Voltage ($V_{MIN}$).

Setting the voltage for the minimum speed is accomplished using a simple resistor voltage divider. The criteria for the voltage divider in this design is that it draw no more than 100 $\mu$A of current. The required minimum speed voltage was determined earlier in the selection of the $V_{IN}$ voltage at 40% duty cycle, since this was also set at the temperature which minimum speed is to occur (20°C).

- $V_{MIN} = 1.76V$

Given this desired setpoint, and knowing the desired divider current, the following equations can be used to solve for the resistor values for $R_3$ and $R_4$:

$$I_{DIV} = \frac{5V}{R_3 + R_4}$$

$$V_{MIN} = \frac{5V \times R_4}{R_3 + R_4}$$

Using the equations above, the resistor values for $R_3$ and $R_4$ are found to be:

- $R_3 = 32.4 k\Omega$
- $R_4 = 17.6 k\Omega$
Using standard 1% resistor values yields the following values:
- $R_3 = 32.4 \, \text{k}\Omega$
- $R_4 = 17.8 \, \text{k}\Omega$

**Step 6: Selecting the Fan Drive Device ($Q_1$).**

Since the fan operating current is below 200 mA, a transistor or MOSFET can be used as the fan drive device. In order to reduce component count and current draw, the drive device for this design is chosen to be a N-channel MOSFET. Selecting from Table 5-2, there are two MOSFETs that are good choices: the MGSF1N02E and the SI2302. These devices have the same pinout and are interchangeable for this design.

**Step 7: Selecting the $R_{\text{SENSE}}$ and $C_{\text{SENSE}}$ Values.**

The goal again for selecting these values is to ensure that the signal at the SENSE pin is 90 mV in amplitude under all operating conditions. This will ensure that the pulses are detected by the TC642B/TC647B device and that the fan operation is detected.

The fan current waveform is shown in Figure 5-8 and, as discussed previously, with a waveform of this shape, the current sense resistor values shown in Table 5-1 are good reference values. Given that the average fan operating current was measured to be 120 mA, this falls between two of the values listed in the table. For reference purposes, both values have been tested and these results are shown in Figures 5-11 (4.7\,\Omega) and 5-12 (3.0\,\Omega). The selected $C_{\text{SENSE}}$ value is 0.1 \,\mu F as this provides the appropriate coupling of the voltage to the SENSE pin.

**FIGURE 5-11:** SENSE pin voltage with 4.7\,\Omega sense resistor.

**FIGURE 5-12:** SENSE pin voltage with 3.0\,\Omega sense resistor.

Since the 3.0\,\Omega value of sense resistor provides the proper voltage to the SENSE pin, it is the correct choice for this solution as it will also provide the lowest power dissipation and the most voltage to the fan. Using the RMS fan current that was measured previously, the power dissipation in the resistor during a fan fault condition is 71 mW ($I_{\text{rms}}^2 \, R_{\text{SENSE}}$). This number will set the wattage rating of the resistor that is selected. The selected value will vary depending upon the derating guidelines that are used.

Now that all the values have been selected, the schematic representation of this design can be seen in Figure 5-13.
Bypass capacitor $C_{VDD}$ is added to the design to decouple the bias voltage. This is good to have, especially when using a MOSFET as the drive device. This helps to give a localized low-impedance source for the current required to charge the gate capacitance of $Q_1$. Two other bypass capacitors, labeled as $C_B$, were also added to decouple the $V_{IN}$ and $V_{MIN}$ nodes. These were added simply to remove any noise present that might cause false triggerings or PWM jitter. $R_5$ is the pull-up resistor for the FAULT output. The value for this resistor is system-dependent.
6.0 PACKAGING INFORMATION

6.1 Package Marking Information

Legend:  
XX...X  Customer specific information*  
Y       Year code (last digit of calendar year)  
YY      Year code (last 2 digits of calendar year)  
WW      Week code (week of January 1 is week ’01’)  
NNN     Alphanumeric traceability code

Note: In the event the full Microchip part number cannot be marked on one line, it will be carried over to the next line thus limiting the number of available characters for customer specific information.

* Standard device marking consists of Microchip part number, year code, week code, and traceability code.

§ Significant Characteristic

Notes:
Dimensions D and E1 do not include mold flash or protrusions. Mold flash or protrusions shall not exceed .010” (0.254mm) per side.
JEDEC Equivalent: MS-012
Drawing No. C04-057
8-Lead Plastic Micro Small Outline Package (MS) (MSOP)

Dimensions D and E1 do not include mold flash or protrusions. Mold flash or protrusions shall not exceed .010" (0.254mm) per side.

JEDEC Equivalent: MO-187

Drawing No. C04-111

- TC647BEPA: PDIP package.
- TC647BEUA: MSOP package.
- TC647BEUATR: Tape and Reel, MSOP package.

Sales and Support

Data Sheets
Products supported by a preliminary Data Sheet may have an errata sheet describing minor operational differences and recommended workarounds. To determine if an errata sheet exists for a particular device, please contact one of the following:

1. Your local Microchip sales office
2. The Microchip Corporate Literature Center U.S. FAX: (480) 792-7277
3. The Microchip Worldwide Site (www.microchip.com)

Please specify which device, revision of silicon and Data Sheet (include Literature #) you are using.

Customer Notification System
Register on our web site (www.microchip.com/cn) to receive the most current information on our products.
Note the following details of the code protection feature on Microchip devices:

- Microchip products meet the specification contained in their particular Microchip Data Sheet.
- Microchip believes that its family of products is one of the most secure families of its kind on the market today, when used in the intended manner and under normal conditions.
- There are dishonest and possibly illegal methods used to breach the code protection feature. All of these methods, to our knowledge, require using the Microchip products in a manner outside the operating specifications contained in Microchip's Data Sheets. Most likely, the person doing so is engaged in theft of intellectual property.
- Microchip is willing to work with the customer who is concerned about the integrity of their code.
- Neither Microchip nor any other semiconductor manufacturer can guarantee the security of their code. Code protection does not mean that we are guaranteeing the product as "unbreakable."

Code protection is constantly evolving. We at Microchip are committed to continuously improving the code protection features of our products. Attempts to break microchip's code protection feature may be a violation of the Digital Millennium Copyright Act. If such acts allow unauthorized access to your software or other copyrighted work, you may have a right to sue for relief under that Act.

Information contained in this publication regarding device applications and the like is intended through suggestion only and may be superseded by updates. It is your responsibility to ensure that your application meets with your specifications. No representation or warranty is given and no liability is assumed by Microchip Technology Incorporated with respect to the accuracy or use of such information, or infringement of patents or other intellectual property rights arising from such use or otherwise. Use of Microchip’s products as critical components in life support systems is not authorized except with express written approval by Microchip. No licenses are conveyed, implicitly or otherwise, under any intellectual property rights.

Microchip received QS-9000 quality system certification for its worldwide headquarters, design and wafer fabrication facilities in Chandler and Tempe, Arizona in July 1999 and Mountain View, California in March 2002. The Company’s quality system processes and procedures are QS-9000 compliant for its PICmicro® 8-bit MCUs, dsPIC® code hopping devices, Serial EEPROMs, microperipherals, non-volatile memory and analog products. In addition, Microchip’s quality system for the design and manufacture of development systems is ISO 9001 certified.

Trademarks

The Microchip name and logo, the Microchip logo, KEELOQ, MPLAB, PIC, PICmicro, PICSTART, PRO MATE and PowerSmart are registered trademarks of Microchip Technology Incorporated in the U.S.A. and other countries.

FilterLab, microID, MXDEV, MXLAB, PICMASTER, SEEVAL and The Embedded Control Solutions Company are registered trademarks of Microchip Technology Incorporated in the U.S.A.

Accuron, Application Maestro, dsPIC, dsPICDEM, dsPICDEM.net, ECONOMONITOR, FanSense, FlexROM, fuzzyLAB, In-Circuit Serial Programming, ICSP, ICEPIC, microPort, Migratable Memory, MPASM, MPLIB, MPLINK, MPSIM, PICC, PICKit, PICDEM, PICDEM.net, PowerCal, PowerInfo, PowerMate, PowerTool, rfLAB, rfPIC, Select Mode, SmartSensor, SmartShunt, SmartTel and Total Endurance are trademarks of Microchip Technology Incorporated in the U.S.A. and other countries.

Serialized Quick Turn Programming (SQTP) is a service mark of Microchip Technology Incorporated in the U.S.A.

All other trademarks mentioned herein are property of their respective companies.
