MCP4801/4811/4821

8/10/12-Bit Voltage Output Digital-to-Analog Converter with Internal $V_{\text{REF}}$ and SPI Interface

**Features**

- MCP4801: 8-Bit Voltage Output DAC
- MCP4811: 10-Bit Voltage Output DAC
- MCP4821: 12-Bit Voltage Output DAC
- Rail-to-Rail Output
- SPI Interface with 20 MHz Clock Support
- Simultaneous Latching of the DAC Output with LDAC Pin
- Fast Settling Time of 4.5 µs
- Selectable Unity or 2x Gain Output
- 2.048V Internal Voltage Reference
- 50 ppm/°C $V_{\text{REF}}$ Temperature Coefficient
- 2.7V to 5.5V Single-Supply Operation
- Extended Temperature Range: -40°C to +125°C

**Applications**

- Set Point or Offset Trimming
- Sensor Calibration
- Precision Selectable Voltage Reference
- Portable Instrumentation (Battery-Powered)
- Calibration of Optical Communication Devices

**Note 1:** The products listed here have similar AC/DC performances.

The MCP4801/4811/4821 devices are single channel 8-bit, 10-bit and 12-bit buffered voltage output Digital-to-Analog Converters (DACs), respectively. The devices operate from a single 2.7V to 5.5V supply with an SPI compatible Serial Peripheral Interface.

The devices have a high precision internal voltage reference ($V_{\text{REF}} = 2.048V$). The user can configure the full-scale range of the device to be 2.048V or 4.096V by setting the Gain Selection Option bit (gain of 1 or 2).

The devices can be operated in Active or Shutdown mode by setting a Configuration register bit or using the SHDN pin. In Shutdown mode, most of the internal circuits, including the output amplifier, are turned off for power savings, while the amplifier output ($V_{\text{OUT}}$) stage is configured to present a known high resistance output load (500 kΩ, typical).

The devices include double-buffered registers, allowing a synchronous update of the DAC output using the LDAC pin. These devices also incorporate a Power-on Reset (POR) circuit to ensure reliable power-up.

The devices utilize a resistive string architecture, with its inherent advantages of low DNL error, low ratio metric temperature coefficient and fast settling time. These devices are specified over the extended temperature range (+125°C).

The devices provide high accuracy and low noise performance for consumer and industrial applications where calibration or compensation of signals (such as temperature, pressure and humidity) are required.

The MCP4801/4811/4821 devices are available in the PDIP, SOIC, MSOP and DFN packages.

1.0 ELECTRICAL CHARACTERISTICS

Absolute Maximum Ratings †

$V_{DD}$ ................................................................. 6.5V
All inputs and outputs ..................... $V_{SS} - 0.3V$ to $V_{DD} + 0.3V$
Current at Input Pins .............................................. $\pm 2$ mA
Current at Supply Pins ................................. $\pm 50$ mA
Current at Output Pins ....................................... $\pm 25$ mA
Storage temperature ............................. $-65^\circ C$ to $+150^\circ C$
Ambient temp. with power applied .......... $-55^\circ C$ to $+125^\circ C$
ESD protection on all pins ............ $\geq 4$ kV (HBM), $\geq 400$ V (MM)
Maximum Junction Temperature ($T_J$) ......... $+150^\circ C$

† Notice: Stresses above those listed under “Maximum Ratings” may cause permanent damage to the device. This is a stress rating only and functional operation of the device at those or any other conditions above those indicated in the operational listings of this specification is not implied. Exposure to maximum rating conditions for extended periods may affect device reliability.

ELECTRICAL CHARACTERISTICS

**Electrical Specifications:** Unless otherwise indicated, $V_{DD} = 5V$, $V_{SS} = 0V$, $V_{REF} = 2.048V$, Output Buffer Gain ($G$) = 2x, $RL = 5\, k\Omega$ to GND, $C_L = 100\, p\Omega$, $T_A = -40$ to $+85^\circ C$. Typical values are at $+25^\circ C$.

### 3.1 Supply Voltage Pins (VDD, VSS)

VDD is the positive supply voltage input pin. The input supply voltage is relative to VSS and can range from 2.7V to 5.5V. The power supply at the VDD pin should be as clean as possible for good DAC performance. Using an appropriate bypass capacitor of about 0.1 µF (ceramic) to ground is recommended. An additional 10 µF capacitor (tantalum) in parallel is also recommended to further attenuate high-frequency noise present in application boards.

VSS is the analog ground pin and the current return path of the device. The user must connect the VSS pin to a ground plane through a low-impedance connection. If an analog ground path is available in the application Printed Circuit Board (PCB), it is highly recommended that the VSS pin be tied to the analog ground path or isolated within an analog ground plane of the circuit board.

### 3.2 Chip Select (CS)

CS is the Chip Select input pin, which requires an active low to enable serial clock and data functions.

### 3.3 Serial Clock Input (SCK)

SCK is the SPI compatible serial clock input pin.

### 3.4 Serial Data Input (SDI)

SDI is the SPI compatible serial data input pin.

### 3.5 Latch DAC Input (LDAC)

LDAC (latch DAC synchronization input) pin is used to transfer the input latch register to the DAC register (output latches, VOUT). When this pin is low, VOUT is updated with input register content. This pin can be tied to low (VSS) if the VOUT update is desired at the rising edge of the CS pin. This pin can be driven by an external control device such as an MCU I/O pin.

### 3.6 Analog Output (VOUT)

VOUT is the DAC analog output pin. The DAC output has an output amplifier. The full-scale range of the DAC output is from VSS to G*VREF, where G is the gain selection option (1x or 2x). The DAC analog output cannot go higher than the supply voltage (VDD).

### 3.7 Exposed Thermal Pad (EP)

There is an internal electrical connection between the exposed thermal pad (EP) and the VSS pin. They must be connected to the same potential on the PCB.
4.0 GENERAL OVERVIEW

The MCP4801, MCP4811 and MCP4821 are single channel voltage-output 8-bit, 10-bit and 12-bit DAC devices, respectively. These devices include rail-to-rail output amplifier, internal voltage reference, shutdown and reset-management circuitry. The devices use an SPI serial communication interface and operate with a single supply voltage from 2.7V to 5.5V.

The DAC input coding of these devices is straight binary. Equation 4-1 shows the DAC analog output voltage calculation.

**EQUATION 4-1: ANALOG OUTPUT VOLTAGE (V\text{OUT})**

\[
V_{\text{OUT}} = \frac{(2.048V \times D_n)}{2^n} \times G
\]

Where:

- \(2.048V\) = Internal voltage reference
- \(D_n\) = DAC input code
- \(G\) = Gain selection
  - 2 for <GA> bit = 0
  - 1 for <GA> bit = 1
- \(n\) = DAC Resolution
  - 8 for MCP4801
  - 10 for MCP4811
  - 12 for MCP4821

The ideal output range of each device is:

- **MCP4801 (n = 8)**
  - (a) 0.0V to 255/256 * 2.048V when gain setting = 1x.
  - (b) 0.0V to 255/256 * 4.096V when gain setting = 2x.

- **MCP4811 (n = 10)**
  - (a) 0.0V to 1023/1024 * 2.048V when gain setting = 1x.
  - (b) 0.0V to 1023/1024 * 4.096V when gain setting = 2x.

- **MCP4821 (n = 12)**
  - (a) 0.0V to 4095/4096 * 2.048V when gain setting = 1x.
  - (b) 0.0V to 4095/4096 * 4.096V when gain setting = 2x.

1 LSb is the ideal voltage difference between two successive codes. Table 4-1 illustrates the LSb calculation of each device.

4.0.1 INL ACCURACY

Integral Non-Linearity (INL) error is the maximum deviation between an actual code transition point and its corresponding ideal transition point once offset and gain errors have been removed. The two endpoints method (from 0x000 to 0xFFF) is used for the calculation. Figure 4-1 shows the details.

A positive INL error represents transition(s) later than ideal. A negative INL error represents transition(s) earlier than ideal.
4.0.2 DNL ACCURACY
A Differential Non-Linearity (DNL) error is the measure of the variations in code widths from the ideal code width. A DNL error of zero indicates that every code is exactly 1 LSb wide.

4.0.3 OFFSET ERROR
Offset error is the deviation from zero voltage output when the digital input code is zero.

4.0.4 GAIN ERROR
Gain error is the deviation from the ideal output, $V_{REF} - 1$ LSb, excluding the effects of offset error.

4.1 Circuit Descriptions

4.1.1 OUTPUT AMPLIFIER
The analog DAC output is buffered with a low-power, precision CMOS amplifier. This amplifier provides low offset voltage and low noise. The output stage enables the device to operate with output voltages close to the power supply rails. Refer to Section 1.0 “Electrical Characteristics” for the analog output voltage range and load conditions.

In addition to resistive load-driving capability, the amplifier will also drive high capacitive loads without oscillation. The amplifier’s strong output allows $V_{OUT}$ to be used as a programmable voltage reference in a system.

4.1.1.1 Programmable Gain Block
The rail-to-rail output amplifier has two configurable gain options: a gain of 1x ($<\text{GA}> = 1$) or a gain of 2x ($<\text{GA}> = 0$). The default setting is a gain of 2x. This results in an ideal full-scale output of 0.000V to 4.096V due to the internal reference ($V_{REF} = 2.048V$).

4.1.2 VOLTAGE REFERENCE
The MCP4801/4811/4821 devices utilize internal 2.048V voltage reference. The voltage reference has a low temperature coefficient and low noise characteristics. Refer to Section 1.0 “Electrical Characteristics” for the voltage reference specifications.
4.1.3 POWER-ON RESET CIRCUIT

The internal Power-on Reset (POR) circuit monitors the power supply voltage ($V_{DD}$) during the device operation. The circuit also ensures that the DAC powers up with high output impedance ($<\text{SHDN}> = 0$, typically 500 kΩ). The devices will continue to have a high-impedance output until a valid write command is received, and the $\overline{DAC}$ pin meets the input low threshold.

If the power supply voltage is less than the POR threshold ($V_{POR} = 2.0V$, typical), the DAC will be held in the Reset state. It will remain in that state until $V_{DD} > V_{POR}$ and a subsequent write command is received.

Figure 4-3 shows a typical power supply transient pulse and the duration required to cause a reset to occur, as well as the relationship between the duration and trip voltage. A 0.1 µF decoupling capacitor, mounted as close as possible to the $V_{DD}$ pin, can provide additional transient immunity.

4.1.4 SHUTDOWN MODE

The user can shut down the device using a software command ($<\text{SHDN}> = 0$) or $\overline{SHDN}$ pin. During shutdown mode, most of the internal circuits, including the output amplifier, are turned off for power savings. The internal reference is not affected by the shutdown command. The serial interface also remains active, allowing a write command to bring the device out of Shutdown mode. There will be no analog output at the $V_{OUT}$ pin, which is internally switched to a known resistive load (500 kΩ, typical). Figure 4-4 shows the analog output stage during Shutdown mode.

The condition of the Power-on Reset circuit during Shutdown is as follows:

a) TURNED OFF IF SHUTDOWN OCCURRED FROM THE $\overline{SHDN}$ PIN

b) REMAINS TURNED ON IF THE SHUTDOWN OCCURRED THROUGH SOFTWARE

The device will remain in Shutdown mode until the $<\text{SHDN}>$ bit = 1 is latched into the device or $\overline{SHDN}$ pin is changed to logic high. When the device is changed from Shutdown to Active mode, the output settling time takes < 10 µs, but greater than the standard active mode settling time (4.5 µs).

FIGURE 4-3: Typical Transient Response.
5.0 SERIAL INTERFACE

5.1 Overview

The MCP4801/4811/4821 devices are designed to interface directly with the Serial Peripheral Interface (SPI) port, available on many microcontrollers, and supports Mode 0,0 and Mode 1,1. Commands and data are sent to the device via the SDI pin, with data being clocked-in on the rising edge of SCK. The communications are unidirectional and, thus, data cannot be read out of the MCP4801/4811/4821 devices. The CS pin must be held low for the duration of a write command. The write command consists of 16 bits and is used to configure the DAC’s control and data latches. Register 5-1 to Register 5-3 detail the input register that is used to configure and load the DAC register for each device. Figure 5-1 to Figure 5-3 show the write command for each device.

Refer to Figure 1-1 and the SPI Timing Specifications Table for detailed input and output timing specifications for both Mode 0,0 and Mode 1,1 operation.

5.2 Write Command

The write command is initiated by driving the CS pin low, followed by clocking the four Configuration bits and the 12 data bits into the SDI pin on the rising edge of SCK. The CS pin is then raised, causing the data to be latched into the DAC’s input register.

The MCP4801/4811/4821 devices utilize a double-buffered latch structure to allow the DAC output to be synchronized with the LDAC pin, if desired.

By bringing down the LDAC pin to a low state, the content stored in the DAC’s input register is transferred into the DAC’s output register ($V_{OUT}$), and $V_{OUT}$ is updated.

All writes to the MCP4801/4811/4821 devices are 16-bit words. Any clocks after the first 16th clock will be ignored. The Most Significant four bits are Configuration bits. The remaining 12 bits are data bits. No data can be transferred into the device with CS high. The data transfer will only occur if 16 clocks have been transferred into the device. If the rising edge of CS occurs prior, shifting of data into the input register will be aborted.

6.0 TYPICAL APPLICATIONS

The MCP4801/4811/4821 family of devices are general purpose, single channel voltage output DACs for various applications where a precision operation with low-power and internal voltage reference is required. Applications generally suited for the devices are:

- Set Point or Offset Trimming
- Sensor Calibration
- Precision Selectable Voltage Reference
- Portable Instrumentation (Battery-Powered)
- Calibration of Optical Communication Devices

6.1 Digital Interface

The MCP4801/4811/4821 devices utilize a 3-wire synchronous serial protocol to transfer the DAC’s setup and input codes from the digital devices. The serial protocol can be interfaced to SPI or Microwire peripherals which are common on many microcontroller units (MCUs), including Microchip’s PIC® MCUs and dsPIC® DSCs.

In addition to the three serial connections (CS, SCK and SDI), the LDAC signal synchronizes the DAC output with LDAC pin event. By bringing the LDAC pin down “low”, the DAC input codes and settings in the DAC input register are latched into the output register, and the DAC analog output is updated. Figure 6-1 shows an example of the pin connections. Note that the LDAC pin can be tied low (VSS) to reduce the required connections from 4 to 3 I/O pins. In this case, the DAC output can be immediately updated when a valid 16 clock transmission has been received and the CS pin has been raised.

6.2 Power Supply Considerations

The typical application will require a bypass capacitor to filter out noise in the power supply traces. The noise can be induced onto the power supply’s traces from various events such as digital switching or as a result of changes on the DAC’s output. The bypass capacitor helps minimize the effect of these noise sources. Figure 6-1 illustrates an appropriate bypass strategy. In this example, two bypass capacitors are used in parallel: (a) 0.1 µF (ceramic) and (b)10 µF (tantalum). These capacitors should be placed as close to the device power pin (VDD) as possible (within 4 mm).

The power source supplying these devices should be as clean as possible. If the application circuit has separate digital and analog power supplies, VDD and VSS of the device should reside on the analog plane.

6.3 Output Noise Considerations

The voltage noise density (in µV/√Hz) is illustrated in Figure 2-13. This noise appears at VOUT and is primarily a result of the internal reference voltage. Its 1/f corner (fCORNER) is approximately 400 Hz. Figure 2-14 illustrates the voltage noise (in mV_RMS or mV_PP). A small bypass capacitor on VOUT is an effective method to produce a single-pole Low-Pass Filter (LPF) that will reduce this noise. For instance, a bypass capacitor sized to produce a 1 kHz LPF would result in an ENREF of about 100 µV_RMS. This would be necessary when trying to achieve the low DNL error performance (at G = 1x) that the MCP4801/4811/4821 devices are capable of. The tested range for stability is .001 µF through 4.7 µF.

6.4 Layout Considerations

Inductively-coupled AC transients and digital switching noises can degrade the output signal integrity, and potentially reduce the device performance. Careful board layout will minimize these effects and increase the Signal-to-Noise Ratio (SNR). Bench testing has shown that a multi-layer board utilizing a low-inductance ground plane, isolated inputs and isolated outputs with proper decoupling, is critical for the best performance. Particularly harsh environments may require shielding of critical signals.

Breadboards and wire-wrapped boards are not recommended if low noise is desired.
6.5 Single-Supply Operation

The MCP4801/4811/4821 devices are rail-to-rail voltage output DAC devices designed to operate with a \(V_{DD}\) range of 2.7V to 5.5V. Its output amplifier is robust enough to drive small-signal loads directly. Therefore, it does not require any external output buffer for most applications.

6.5.1 DC SET POINT OR CALIBRATION

A common application for the devices is a digitally-controlled set point and/or calibration of variable parameters, such as sensor offset or slope. For example, the MCP4821 and MCP4822 provide 4096 output steps. If \(G = 1x\) is selected, the internal 2.048V \(V_{REF}\) would produce 500 \(\mu\)V of resolution. If \(G = 2x\) is selected, the internal 2.048 \(V_{REF}\) would produce 1 mV of resolution.

6.5.1.1 Decreasing Output Step Size

If the application is calibrating the bias voltage of a diode or transistor, a bias voltage range of 0.8V may be desired with about 200 \(\mu\)V resolution per step. Two common methods to achieve a 0.8V range are to either reduce \(V_{REF}\) to 0.82V (using the MCP49XX family device that uses external reference) or use a voltage divider on the DAC's output.

Using a \(V_{REF}\) is an option if the \(V_{REF}\) is available with the desired output voltage range. However, occasionally, when using a low-voltage \(V_{REF}\), the noise floor causes SNR error that is intolerable. Using a voltage divider method is another option and provides some advantages when \(V_{REF}\) needs to be very low or when the desired output voltage is not available. In this case, a larger value \(V_{REF}\) is used while two resistors scale the output range down to the precise desired level.

Example 6-1 illustrates this concept. Note that the bypass capacitor on the output of the voltage divider plays a critical function in attenuating the output noise of the DAC and the induced noise from the environment.

**EXAMPLE 6-1: EXAMPLE CIRCUIT OF SET POINT OR THRESHOLD CALIBRATION**

(a) Single Output DAC:
- MCP4801
- MCP4811
- MCP4821

(b) Dual Output DAC:
- MCP4802
- MCP4812
- MCP4822

\[
V_{OUT} = 2.048 \cdot G \cdot \frac{D_n}{2^N}
\]

\[
V_{trip} = V_{OUT} \left( \frac{R_2}{R_1 + R_2} \right)
\]

G = Gain selection (1x or 2x)

\(D_n\) = Digital value of DAC (0-255) for MCP4801/MCP4802

\(D_n\) = Digital value of DAC (0-1023) for MCP4811/MCP4812

\(D_n\) = Digital value of DAC (0-4095) for MCP4821/MCP4822

N = DAC bit resolution
6.5.1.2 Building a “Window” DAC

When calibrating a set point or threshold of a sensor, typically only a small portion of the DAC output range is utilized. If the LSB size is adequate enough to meet the application’s accuracy needs, the unused range is sacrificed without consequences. If greater accuracy is needed, then the output range will need to be reduced to increase the resolution around the desired threshold.

If the threshold is not near $V_{REF}$, $2V_{REF}$ or $V_{SS}$, then creating a “window” around the threshold has several advantages. One simple method to create this “window” is to use a voltage divider network with a pull-up and pull-down resistor. Example 6-2 and Example 6-4 illustrate this concept.

EXAMPLE 6-2: SINGLE-SUPPLY “WINDOW” DAC

(a) Single Output DAC:
- MCP4801
- MCP4811
- MCP4821

(b) Dual Output DAC:
- MCP4802
- MCP4812
- MCP4822

![Diagram of a single-supply “window” DAC with equations and component values]

Thevenin Equivalent

$$V_{OUT} = 2.048 \cdot G \cdot \frac{D_n}{2^N}$$

- $G =$ Gain selection (1x or 2x)
- $D_n =$ Digital value of DAC (0-255) for MCP4801/MCP4802
- $D_n =$ Digital value of DAC (0-1023) for MCP4811/MCP4812
- $D_n =$ Digital value of DAC (0-4095) for MCP4821/MCP4822
- $N =$ DAC bit resolution

$$V_{R23} = \frac{R_1 R_3}{R_2 + R_3}$$

$$V_{23} = \frac{(V_{CC+} R_2) + (V_{CC-} R_3)}{R_2 + R_3}$$

$$V_{TRIP} = \frac{V_{OUT} R_{23} + V_{23} R_1}{R_1 + R_{23}}$$
6.6 Bipolar Operation

Bipolar operation is achievable using the MCP4801/4811/4821 family of devices by utilizing an external operational amplifier (op amp). This configuration is desirable due to the wide variety and availability of op amps. This allows a general purpose DAC, with its cost and availability advantages, to meet almost any desired output voltage range, power and noise performance.

Example 6-3 illustrates a simple bipolar voltage source configuration. R₁ and R₂ allow the gain to be selected, while R₃ and R₄ shift the DAC’s output to a selected offset. Note that R₄ can be tied to V_DD, instead of V_SS, if a higher offset is desired. Also note that a pull-up to V_DD could be used instead of R₄, or in addition to R₄, if a higher offset is desired.

**EXAMPLE 6-3: DIGITALLY-CONTROLLED BIPOLAR VOLTAGE SOURCE**

(a) Single Output DAC:
- MCP4801
- MCP4811
- MCP4821

(b) Dual Output DAC:
- MCP4802
- MCP4812
- MCP4822

\[
V_{OUT} = 2.048 \cdot G \frac{D_n}{2^N}
\]

\[
V_{IN+} = \frac{V_{OUT}R_3}{R_3 + R_4}
\]

\[
V_O = V_{IN+}(1 + \frac{R_2}{R_1}) - V_{DD}(\frac{R_2}{R_1})
\]

The equation can be simplified to:

\[
\frac{-R_3}{R_1} = \frac{-2.05}{4.096V} \quad \frac{R_2}{R_1} = \frac{1}{2}
\]

If R₁ = 20 kΩ and R₂ = 10 kΩ, the gain will be 0.5.

Step 4: Next solve for R₃ and R₄ by setting the DAC to 4096, knowing that the output needs to be +2.05V.

\[
\frac{R_4}{(R_3 + R_4)} = \frac{2.05V + (0.5 \cdot 4.096V)}{1.5 \cdot 4.096V} = \frac{2}{3}
\]

If R₄ = 20 kΩ, then R₃ = 10 kΩ.

6.6.1 DESIGN EXAMPLE: DESIGN A BIPOLAR DAC USING EXAMPLE 6-3 WITH 12-BIT MCP4821 OR MCP4822

An output step magnitude of 1 mV, with an output range of ±2.05V, is desired for a particular application.

Step 1: Calculate the range: +2.05V – (-2.05V) = 4.1V.

Step 2: Calculate the resolution needed:

\[4.1V/1\text{mV} = 4100\]

Since \(2^{12} = 4096\), 12-bit resolution is desired.

Step 3: The amplifier gain \((R_2/R_1)\), multiplied by full-scale \(V_{OUT}\) (4.096V), must be equal to the desired minimum output to achieve bipolar operation. Since any gain can be realized by choosing resistor values \((R_1+R_2)\), the \(V_{REF}\) value must be selected first. If a \(V_{REF}\) of 4.096V is used \((G=2)\), solve for the amplifier’s gain by setting the DAC to 0, knowing that the output needs to be -2.05V.
6.7 Selectable Gain and Offset Bipolar Voltage Output

In some applications, precision digital control of the output range is desirable. Example 6-4 illustrates how to use the MCP4801/4811/4821 family of devices to achieve this in a bipolar or single-supply application.

EXAMPLE 6-4:  BIPOLAR VOLTAGE SOURCE WITH SELECTABLE GAIN AND OFFSET

This circuit is typically used for linearizing a sensor whose slope and offset varies.

The equation to design a bipolar “window” DAC would be utilized if R3, R4 and R5 are populated.

\[
\begin{align*}
V_{OUTA} &= 2.048 \cdot G \cdot \frac{D_n}{2^N} \\
V_{OUTB} &= 2.048 \cdot G \cdot \frac{D_n}{2^N} \\
V_{IN+} &= \frac{V_{OUTB}R_4 + V_{CC\cdot R_3}}{R_3 + R_4} \\
V_O &= V_{IN+}\left(1 + R_2 \frac{R_3}{R_f}\right) - V_{OUTA}\frac{R_3}{R_f}
\end{align*}
\]

G = Gain selection (1x or 2x)
N = DAC bit resolution
D_n = Digital value of DAC (0-255) for MCP4801
    = Digital value of DAC (0-1023) for MCP4811
    = Digital value of DAC (0-4095) for MCP4821

Thevenin Equivalent

\[
\begin{align*}
V_{45} &= \frac{V_{CC\cdot R_4} + V_{CC\cdot R_5}}{R_4 + R_5} \\
V_{IN+} &= \frac{V_{OUTB}R_{45} + V_{45}R_3}{R_3 + R_{45}} \\
V_O &= V_{IN+}\left(1 + R_2 \frac{R_3}{R_f}\right) - V_{OUTA}\frac{R_3}{R_f}
\end{align*}
\]
6.8 Designing a Double-Precision DAC

Example 6-5 illustrates how to design a single-supply voltage output capable of up to 24-bit resolution by using 12-bit DACs. This design is simply a voltage divider with a buffered output.

As an example, if an application similar to the one developed in Section 6.6.1 “Design Example: Design a Bipolar DAC Using Example 6-3 with 12-bit MCP4821 or MCP4822” required a resolution of 1 µV instead of 1 mV, and a range of 0V to 4.1V, then 12-bit resolution would not be adequate.

Step 1: Calculate the resolution needed:
\[ 4.1V/1 \mu V = 4.1 \times 10^6. \]  
Since \[ 2^{22} = 4.2 \times 10^6, \] 22-bit resolution is desired. Since DNL = ±0.75 LSb, this design can be done with the 12-bit MCP4821 or MCP4822 DAC devices.

Step 2: Since DACB’s VOUTB has a resolution of 1 mV, its output only needs to be “pulled” 1/1000 to meet the 1 µV target. Dividing VOUTA by 1000 would allow the application to compensate for DACB’s DNL error.

Step 3: If R2 is 100kΩ, then R1 needs to be 100 kΩ.

Step 4: The resulting transfer function is shown in the equation of Example 6-5.

**EXAMPLE 6-5: SIMPLE, DOUBLE-PRECISION DAC WITH MCP4821**

\[
\begin{align*}
V_{OUTA} &= 2.048 \cdot G_A \cdot \frac{D_A}{2^{12}} \\
V_{OUTB} &= 2.048 \cdot G_B \cdot \frac{D_B}{2^{12}} \\
V_O &= \frac{V_{OUTA}R_2 + V_{OUTB}R_1}{R_1 + R_2}
\end{align*}
\]

- \( G_x \) = Gain selection (1x or 2x)
- \( D_n \) = Digital value of DAC (0-4096)
6.9 Building Programmable Current Source

Example 6-6 shows an example of building a programmable current source using a voltage follower. The current sensor (sensor resistor) is used to convert the DAC voltage output into a digitally-selectable current source.

Adding the resistor network from Example 6-2 would be advantageous in this application. The smaller $R_{SENSE}$ is, the less power dissipated across it.

**EXAMPLE 6-6: DIGITALLY-CONTROLLED CURRENT SOURCE**

$$I_b = \frac{I_L}{\beta}$$

$$I_L = \frac{V_{OUT}}{R_{sense}} \times \frac{\beta}{\beta + 1}$$

where $\beta = $ Common-Emitter Current Gain.

However, this also reduces the resolution that the current can be controlled with. The voltage divider, or “window”, DAC configuration would allow the range to be reduced, thus increasing resolution around the range of interest. When working with very small sensor voltages, plan on eliminating the amplifier’s offset error by storing the DAC’s setting under known sensor conditions.

(a) Single Output DAC:
- MCP4801
- MCP4811
- MCP4821

(b) Dual Output DAC:
- MCP4802
- MCP4812
- MCP4822

$G = $ Gain selection (1x or 2x)

$D_n = $ Digital value of DAC (0-255) for MCP4801/MCP4802

$ = $ Digital value of DAC (0-1023) for MCP4811/MCP4812

$ = $ Digital value of DAC (0-4095) for MCP4821/MCP4822

$N = $ DAC bit resolution
7.0 DEVELOPMENT SUPPORT

7.1 Evaluation & Demonstration Boards

The Mixed Signal PICtail™ Demo Board supports the MCP4801/4811/4821 family of devices. Refer to www.microchip.com for further information on this product's capabilities and availability.
8.0 PACKAGING INFORMATION

8.1 Package Marking Information

Legend:

- XX...X Customer-specific information
- Y Year code (last digit of calendar year)
- YY Year code (last 2 digits of calendar year)
- WW Week code (week of January 1 is week ‘01’)
- NNN Alphanumeric traceability code
- $\text{e}^3$ Pb-free JEDEC designator for Matte Tin (Sn)
- * This package is Pb-free. The Pb-free JEDEC designator ($\text{e}^3$) can be found on the outer packaging for this package.

Note: In the event the full Microchip part number cannot be marked on one line, it will be carried over to the next line, thus limiting the number of available characters for customer-specific information.
8-Lead Plastic Dual Flat, No Lead Package (MC) – 2x3x0.9 mm Body [DFN]

Examples:

a) MCP4801-E/MC: Extended temperature, DFN package.
b) MCP4801T-E/MC: Extended temperature, DFN package, Tape and Reel.
c) MCP4801-E/MS: Extended temperature, MSOP package.
d) MCP4801T-E/MS: Extended temperature, MSOP package, Tape and Reel.
e) MCP4801-E/P: Extended temperature, PDIP package.
f) MCP4801-E/SN: Extended temperature, SOIC package.
g) MCP4801T-E/SN: Extended temperature, SOIC package, Tape and Reel.

a) MCP4811-E/MC: Extended temperature, DFN package.
b) MCP4811T-E/MC: Extended temperature, DFN package, Tape and Reel.
c) MCP4811-E/MS: Extended temperature, MSOP package.
d) MCP4811T-E/MS: Extended temperature, MSOP package, Tape and Reel.
e) MCP4811-E/P: Extended temperature, PDIP package.
f) MCP4811-E/SN: Extended temperature, SOIC package.
g) MCP4811T-E/SN: Extended temperature, SOIC package, Tape and Reel.

a) MCP4821-E/MC: Extended temperature, DFN package.
b) MCP4821T-E/MC: Extended temperature, DFN package, Tape and Reel.
c) MCP4821-E/MS: Extended temperature, MSOP package.
d) MCP4821T-E/MS: Extended temperature, MSOP package, Tape and Reel.
e) MCP4821-E/P: Extended temperature, PDIP package.
f) MCP4821-E/SN: Extended temperature, SOIC package.
g) MCP4821T-E/SN: Extended temperature, SOIC package, Tape and Reel.
Note the following details of the code protection feature on Microchip devices:

• Microchip products meet the specification contained in their particular Microchip Data Sheet.

• Microchip believes that its family of products is one of the most secure families of its kind on the market today, when used in the intended manner and under normal conditions.

• There are dishonest and possibly illegal methods used to breach the code protection feature. All of these methods, to our knowledge, require using the Microchip products in a manner outside the operating specifications contained in Microchip’s Data Sheets. Most likely, the person doing so is engaged in theft of intellectual property.

• Microchip is willing to work with the customer who is concerned about the integrity of their code.

• Neither Microchip nor any other semiconductor manufacturer can guarantee the security of their code. Code protection does not mean that we are guaranteeing the product as “unbreakable.”

Code protection is constantly evolving. We at Microchip are committed to continuously improving the code protection features of our products. Attempts to break Microchip’s code protection feature may be a violation of the Digital Millennium Copyright Act. If such acts allow unauthorized access to your software or other copyrighted work, you may have a right to sue for relief under that Act.

Information contained in this publication regarding device applications and the like is provided only for your convenience and may be superseded by updates. It is your responsibility to ensure that your application meets with your specifications. MICROCHIP MAKES NO REPRESENTATIONS OR WARRANTIES OF ANY KIND WHETHER EXPRESS OR IMPLIED, WRITTEN OR ORAL, STATUTORY OR OTHERWISE, RELATED TO THE INFORMATION, INCLUDING BUT NOT LIMITED TO ITS CONDITION, QUALITY, PERFORMANCE, MERCHANTABILITY OR FITNESS FOR PURPOSE. Microchip disclaims all liability arising from this information and its use. Use of Microchip devices in life support and/or safety applications is entirely at the buyer's risk, and the buyer agrees to defend, indemnify and hold harmless Microchip from any and all damages, claims, suits, or expenses resulting from such use. No licenses are conveyed, implicitly or otherwise, under any Microchip intellectual property rights.
