32.4 On-Chip Voltage Regulation ......................................................................................32-7
32.5 Related Application Notes............................................................................................32-9
32.6 Revision History ..........................................................................................................32-10
32.1 INTRODUCTION

At their highest level of functionality, PIC24F devices integrate several features that affect the entire device as a whole. They add convenience and flexibility of design for the user, and allow the devices to be incorporated into a wider range of designs. These include:

- Flexible Configuration Options – Allowing users to select a wide range of basic microcontroller operating options and changing them if needed during run time.
- Device Identification – Allowing electronic confirmation of a device part number and revision level in the target application.
- On-Chip Voltage Regulator – Allowing the device to be used over a range of application voltage levels.

32.2 DEVICE CONFIGURATION

The basic behavior and operation of PIC24F devices are set by the device Configuration bits. These allow the user to select a wide range of options and optimize the microcontroller’s operation to the application’s requirements.

In all PIC24F family devices, device Configuration bits are mapped to the device’s program memory space, starting at location F80000h. This is beyond the user program memory space and belongs to the configuration memory space (800000h-FFFFFFh).

The method by which the Configuration bits are programmed differs between major device families. The details are discussed in Section 32.2.1 “PIC24F J-Series Flash Devices” and Section 32.2.2 “PIC24F K-Series Flash Devices”.

Table 32-1 provides a list of the most common Configuration bit options. Note that this is not a comprehensive list; certain device families will have unique configuration options that are specific to its peripheral set. Each Configuration bit and its operation is described in the relevant section of the "PIC24F Family Reference Manual". For more information on Configuration bit mapping of a particular device, refer to the specific device data sheet.

| Note: All the bits that are described here are not available on all the devices. |

32.2.1 PIC24F J-Series Flash Devices

For PIC24F devices with J-series Flash memory, the Configuration bits are implemented as volatile memory; that is, the configuration data must be loaded each time the device is powered up. The actual configuration data is stored in the last several words at the end of the on-chip program memory space, known as the Flash Configuration Words (abbreviated as CW). During all types of device Resets, the configuration data is automatically loaded from the Flash Configuration Words to the proper Configuration registers.

The CWs are 16-bit, packed representations of the actual device Configuration bits; the actual locations of which are distributed among several locations in configuration space. The number of CWs implemented for a particular device family depends on the device’s feature set and configuration options; there are always at least two and occasionally as many as four. They are numbered sequentially, starting from the last address in program memory and working towards lower addresses. Table 32-2 provides the CW address for common program memory sizes. Refer to the device data sheet for part-specific implementation.

The Configuration bits can be programmed (read as ‘0’), or left unprogrammed (read as ‘1’), to select various configuration options. To prevent inadvertent configuration changes during code execution, all programmable device Configuration bits are write-once. After a bit is initially written during a power cycle or any Reset, it cannot be written to again. Any change of a Configuration bit (not a change to a Flash Configuration Word) causes a Configuration Mismatch (CM) Reset, which then forces a reload of the original values.

</table>

Note 1: Only implemented in some device families. CW4, if implemented, is located at the address ([CW3]-2).

32.2.1.1 CONSIDERATIONS WHEN USING FLASH CONFIGURATION WORDS

When creating applications for J-series Flash devices, always specifically allocate the location of the Flash Configuration Word for configuration data. This is to ensure that the program code is not stored in this address when the code is compiled.

The upper byte of all the Flash Configuration Words in the program memory should always be ‘1111 1111’. This makes them appear to be NOP instructions in the remote event that their locations are ever executed by accident. Since the Configuration bits are not implemented in the corresponding locations, writing ‘1’ to these locations has no effect on device operation.

As mentioned before, changes to the actual device Configuration bits during run time would cause a Configuration Mismatch Reset. This does not prevent changes to Flash Configuration Words during normal operation. This also makes it possible for an application to change its hardware configuration by writing new data to these Flash Configuration Words, and then executing a RESET command, which results in reloading the new values.
32.2.2 PIC24F K-Series Flash Devices

For PIC24F devices with K-series Flash memory, the Configuration bits are implemented as a physically separate block of nonvolatile memory. Once programmed, configuration data is maintained indefinitely. Although they act like fuses, the Configuration bits are freely reprogrammable. Since they lie inside the configuration memory space, the Configuration bits are not directly accessible; they can only be written and read using table read and table write instructions.

Unlike the Flash Configuration Words in J-series devices, the Configuration bits in K-series devices are organized into 8-bit registers, always the Least Significant Byte (LSB) of a program memory address. These Configuration registers are symbolically named according to their primary function (i.e., General Segment Protection, Oscillator Selection, etc.). Table 32-3 shows the typical names and addresses of Configuration registers in K-series devices. Note that not all Configuration registers are implemented on all devices, and certain devices with extended feature sets, may have additional registers. In addition, there may be variations in naming or location of registers in certain devices. Refer to the device data sheet for specific information.

Like J-series Flash devices, the Configuration bits can be programmed (read as ‘0’), or left unprogrammed (read as ‘1’), to select various configuration options. Changes to Configuration bits during programming take effect immediately and do not require a device Reset.

The implementation of the Configuration bits in K-series devices makes a Configuration Mismatch (CM) error and Reset during full-speed operation virtually impossible. However, a severe device disturbance (such as an ESD event) during Sleep or Deep Sleep may disrupt the configuration safety check, resulting in a CM Reset.

32.3 DEVICE IDENTIFICATION

PIC24F devices have two read-only registers that provide device-specific identification information. These are located near the end of the device configuration space, starting at FF0000h. Like the Flash Configuration Words, the Device ID registers are 24 bits wide and the upper 8 bits are unimplemented. Both registers can be read using table read instructions.

The DEVID register at FF0000h (Register 32-1) identifies the Microchip microcontroller architectural family and the specific part number. The DEVREV register at FF0002h (Register 32-2) identifies the particular silicon revision for that device in terms of major and minor revision levels ("letter and dot revision" format).

For any given family of PIC24F devices, the corresponding device data sheet provides a list of values for DEVID and the corresponding part numbers for that family. The association of the value of DEVREV to a silicon revision level is different for each part number. The translation of a DEVREV value to a revision level can be found in part-specific literature, such as device errata, or through Microchip's development tools, such as MPLAB® IDE. For assistance with interpreting values of DEVREV, contact Microchip technical support or your local Microchip representative.

32.4 **ON-CHIP VOLTAGE REGULATION**

The PIC24FJ family powers its core digital logic at a nominal 2.5V. This may create an issue for designs that are required to operate at a higher typical voltage, such as 3.3V. To simplify system design, all PIC24FJ family devices incorporate an on-chip regulator that allows the device to run its core logic from VDD.

PIC24FJ family devices use two different control systems to control the on-chip regulators. In some devices, the regulator is enabled by supplying VDD to the control pin, while in some devices, the regulator is disabled when the control pin is supplied with VDD. If the regulator is enabled when VDD is supplied, the control pin is named ENVREG. If the regulator is disabled when VDD is supplied, the control pin is named DISVREG.

When enabled, the regulator draws power from the VDD pins to provide power to the digital logic. When disabled, power for the core logic must be supplied to the device on the VDDCORE/VCAP pin. This can be done by supplying separate VDD and VDDCORE voltage to allow the I/O pins to run at higher voltage levels (nominal 2.5V and 3.3V for VDDCORE and VDD, respectively). If the higher voltage is not required, the VDDCORE/VCAP and VDD pins can be tied together to operate at a lower nominal voltage. Refer to the device data sheet for device-specific voltage limitations.

If the regulator is enabled, a capacitor with a low, effective, series resistance (made of tantalum or ceramic) must be connected to the VDDCORE/VCAP pin. This helps maintain the stability of the regulator. The recommended values for the filter capacitor and its ESR (Equivalent Series Resistance) are provided in the Electrical Characteristics section of the specific device data sheet.

Possible configurations for both positive enable and positive disable regulators are provided in Figure 32-1.

### 32.4.1 On-Chip Regulator and Power-on Reset (POR)

When the voltage regulator is enabled, it takes approximately 20 μs for it to generate output from the point where VDD attains the stability. During this time, designated as TSTARTUP, code execution is disabled. TSTARTUP is applied every time the device resumes operation after any Power-Down modes and Sleep mode.

If the regulator is disabled, a separate Power-up Timer (PWRT) is automatically enabled. The PWRT adds a fixed delay of 64 ms nominal delay at device start-up.

### 32.4.2 On-Chip Regulator and Brown-out Reset (BOR)

When the on-chip regulator is enabled, the PIC24F family devices also have a simple brown-out capability. If the voltage supplied to the regulator is inadequate to maintain device operation, the regulator Reset circuitry will generate a Brown-out Reset. This event is captured by the BOR flag bit (RCON<1>). The brown-out voltage levels are listed in the specific device data sheet.

### 32.4.3 Voltage Regulator Tracking Mode

When the on-chip regulator is enabled, the regulator provides a constant voltage of 2.5V nominal to the digital core logic. The regulator can provide this level from a VDD of about 2.7V all the way up to the device’s VDDMAX. It does not have the capability to rise the regulator output voltage to 2.5V when the VDD drops below 2.5V. In order to prevent “brown-out” conditions when the voltage drops too low for the regulator, devices with the Low-Voltage Detect (LVD) feature enter a Tracking mode. In Tracking mode, the regulator output follows VDD, with a typical voltage drop of 100 mV.
When the device enters Tracking mode, it is no longer possible to operate at full speed. To provide information on when the device enters Tracking mode, the on-chip regulator includes a simple, Low-Voltage Detect circuit. When VDD drops below full-speed operating voltage, the circuit sets the Low-Voltage Detect Interrupt Flag, LVDIF. This can be used to generate an interrupt and put the application into a low-power operational mode or trigger an orderly shutdown. Low-Voltage Detection is only available when the regulator is enabled. If VDD drops below minimum Tracking mode voltage, a Brown-out Reset will be generated. Refer to the Electrical Characteristics section of the specific device data sheet to find the LVD trip point and the BOR trip point.

Note 1: These are typical operating voltages. Refer to the Electrical Characteristics in the specific device data sheet for the full operating ranges of VDD and VDDCORE.
32.5 RELATED APPLICATION NOTES

This section lists application notes that are related to this section of the manual. These application notes may not be written specifically for the PIC24F device family, but the concepts are pertinent and could be used with modification and possible limitations. The current application notes related to the High-Level Device Integration are:

<table>

Note: Please visit the Microchip web site (www.microchip.com) for additional application notes and code examples for the PIC24F family of devices.
32.6  REVISION HISTORY

Revision A (January 2007)
This is the initial released revision of this document.

Revision B (March 2008)
Minor edits to text throughout document.

Revision C (January 2010)
Updated Section 32.2 “Device Configuration” with new information on device configuration for K-series Flash devices, and reorganization of information on J-series Flash devices.
Minor re-ordering of other topics.

Revision D (May 2010)
This revision includes the following updates:
• Added a shaded note to the second paragraph of 32.4 “On-Chip Voltage Regulation” regarding availability of the ENVREG/DISVREG pins
Note the following details of the code protection feature on Microchip devices:

- Microchip products meet the specification contained in their particular Microchip Data Sheet.
- Microchip believes that its family of products is one of the most secure families of its kind on the market today, when used in the intended manner and under normal conditions.
- There are dishonest and possibly illegal methods used to breach the code protection feature. All of these methods, to our knowledge, require using the Microchip products in a manner outside the operating specifications contained in Microchip’s Data Sheets. Most likely, the person doing so is engaged in theft of intellectual property.
- Microchip is willing to work with the customer who is concerned about the integrity of their code.
- Neither Microchip nor any other semiconductor manufacturer can guarantee the security of their code. Code protection does not mean that we are guaranteeing the product as “unbreakable.”

Code protection is constantly evolving. We at Microchip are committed to continuously improving the code protection features of our products. Attempts to break Microchip’s code protection feature may be a violation of the Digital Millennium Copyright Act. If such acts allow unauthorized access to your software or other copyrighted work, you may have a right to sue for relief under that Act.

Information contained in this publication regarding device applications and the like is provided only for your convenience and may be superseded by updates. It is your responsibility to ensure that your application meets with your specifications. MICROCHIP MAKES NO REPRESENTATIONS OR WARRANTIES OF ANY KIND WHETHER EXPRESS OR IMPLIED, WRITTEN OR ORAL, STATUTORY OR OTHERWISE, RELATED TO THE INFORMATION, INCLUDING BUT NOT LIMITED TO ITS CONDITION, QUALITY, PERFORMANCE, MERCHANTABILITY OR FITNESS FOR PURPOSE. Microchip disclaims all liability arising from this information and its use. Use of Microchip devices in life support and/or safety applications is entirely at the buyer’s risk, and the buyer agrees to defend, indemnify and hold harmless Microchip from any and all damages, claims, suits, or expenses resulting from such use. No licenses are conveyed, implicitly or otherwise, under any Microchip intellectual property rights.
