1.0 DEVICE OVERVIEW

This document defines the programming specification for the PIC24FJXXXDA1/DA2/GB2/GA3/GC0 families of 16-bit microcontrollers (MCUs). This programming specification is required only for those developing programming support for the PIC24FJXXXDA1/DA2/GB2/GA3/GC0 families. Customers using only one of these devices should use development tools that already provide support for device programming.

This specification includes programming specifications for the following devices:

- PIC24FJ128DA106
- PIC24FJ128DA110
- PIC24FJ128DA206
- PIC24FJ128DA210
- PIC24FJ128GB206
- PIC24FJ128GB210
- PIC24FJ64GA310
- PIC24FJ64GA308
- PIC24FJ64GA306
- PIC24FJ64GC010
- PIC24FJ64GC008
- PIC24FJ64GC006

- PIC24FJ256DA106
- PIC24FJ256DA110
- PIC24FJ256DA206
- PIC24FJ256DA210
- PIC24FJ256GB206
- PIC24FJ256GB210
- PIC24FJ128GA310
- PIC24FJ128GA308
- PIC24FJ128GA306
- PIC24FJ128GC010
- PIC24FJ128GC008
- PIC24FJ128GC006

Topics covered include:

1.0 Device Overview .......................................................1
2.0 Programming Overview of the PIC24FJXXXDA1/DA2/GB2/GA3/GC0 Families ........ 2
3.0 Device Programming – ICSP ...................................18
4.0 Device Programming – Enhanced ICSP ..................33
5.0 The Programming Executive ...................................51
6.0 Device Details .........................................................63
7.0 AC/DC Characteristics and Timing Requirements........ 66
2.0 PROGRAMMING OVERVIEW OF THE PIC24FJXXXDA1/DA2/GB2/GA3/GC0 FAMILIES

There are two methods of programming the PIC24FJXXXDA1/DA2/GB2/GA3/GC0 families of devices discussed in this programming specification. They are:

- In-Circuit Serial Programming™ (ICSP™)
- Enhanced In-Circuit Serial Programming (Enhanced ICSP)

The ICSP programming method is the most direct method to program the device; however, it is also the slower of the two methods. It provides native, low-level programming capability to erase, program and verify the chip.

The Enhanced In-Circuit Serial Programming (Enhanced ICSP) protocol uses a faster method that takes advantage of the Programming Executive (PE), as illustrated in Figure 2-1. The Programming Executive provides all the necessary functionality to erase, program and verify the chip through a small command set. The command set allows the programmer to program the PIC24FJXXXDA1/DA2/GB2/GA3/GC0 MCUs without having to deal with the low-level programming protocols of the chip.

FIGURE 2-1: PROGRAMMING SYSTEM OVERVIEW FOR ENHANCED ICSP™

This specification is divided into major sections that describe the programming methods independently. 

**Section 3.0 “Device Programming – ICSP”** describes the In-Circuit Serial Programming method. **Section 4.0 “Device Programming – Enhanced ICSP”** describes the Run-Time Self-Programming (RTSP) method.

---

**Note:** The address of Special Function Register, TBLPAG, has changed from 0x32 to 0x54 in PIC24FJXXXDA1/DA2/GB2/GA3/GC0 family devices.

In those cases where legacy programming specification code from other device families is used as a basis to implement the PIC24FJXXXDA1/DA2/GB2/GA3/GC0 families’ programming specification, special care must be taken to ensure all references to TBLPAG, in any existing code, are updated with the correct opcode hex data for the mnemonic and operands (as shown below).

2.1 Power Requirements

All PIC24FJXXXDA1/DA2/GB2/GA3/GC0 devices power their core digital logic at a nominal 1.8V. To simplify system design, all devices in the PIC24FJXXXDA1/DA2/GB2/GA3/GC0 families incorporate an on-chip regulator that allows the device to run its core logic from VDD. For the PIC24FJ128GA310 and PIC24FJ128GC010 families, the regulator is always enabled, so there is no ENVREG pin on these devices.

The regulator provides power to the core from the other VDD pins. A low-ESR capacitor (such as ceramic or tantalum) must be connected to the VCAP pin (see Table 2-1 and Figure 2-2). This helps to maintain the stability of the regulator. The specifications for core voltage and capacitance are listed in Section 7.0 “AC/DC Characteristics and Timing Requirements”.

2.2 Program Memory Write/Erase Requirements

The Flash program memory on PIC24FJXXXDA1/DA2/GB2/GA3/GC0 devices has a specific write/erase requirement that must be adhered to for proper device operation. Any given word in memory must not be written more than twice before erasing the page where it is located. Thus, the easiest way to conform to this rule is to write all of the data in a programming block, within one write cycle. The programming methods specified in this specification comply with this requirement.

Table: Writing to a location multiple times without erasing is not recommended.

Note:

2.3 Writing to a location multiple times without erasing is not recommended.

<td>Programming Pin Pairs 1, 2 and 3: Serial Data</td>
<td></td>
</tr>
</tbody>
</table>

Legend: I = Input, O = Output, P = Power

Note 1: There is no ENVREG pin in the PIC24FJ128GA310 and PIC24FJ128GC010 families. The regulator is always enabled and the ENVREG pin is replaced by the VBAT pin. It is recommended to connect the VBAT pin to the battery or VDD during programming.

Note 2: All power supply and ground pins must be connected, including analog supplies and ground (AVDD/AVSS and SVDD/SVSS, where implemented).
2.3 Pin Diagrams

Figure 2-4 through Figure 2-17 provide the pin diagrams for the PIC24FJXXDA1/DA2/GB2/GA3/GC0 families. The pins that are required for programming are listed in Table 2-1 and are indicated in bold text in the figures. Refer to the appropriate device data sheet for complete pin descriptions.

2.3.1 PGECx AND PGEDx PIN PAIRS

All of the devices in the PIC24FJXXDA1/DA2/GB2/GA3/GC0 families have three separate pairs of programming pins, labelled as PGEC1/PGED1, PGEC2/PGED2 and PGEC3/PGED3. Any one of these pin pairs may be used for device programming by either ICSP or Enhanced ICSP. Unlike voltage supply and ground pins, it is not necessary to connect all three pin pairs to program the device. However, the programming method must use both pins of the same pair.

2.4 Memory Map

The program memory map extends from 000000h to FFFFFFFEh. Code storage is located at the base of the memory map and supports up to 87K instruction words (about 256 Kbytes). Table 2-2 provides the program memory size, and number of erase and program blocks present in each device variant. Each erase block, or page, contains 512 instructions, and each program block, or row, contains 64 instructions.

Locations, 800000h through 8007FEh, are reserved for executive code memory. This region stores the Programming Executive and the Debugging Executive. The Programming Executive is used for device programming and the Debugging Executive is used for in-circuit debugging. This region of memory cannot be used to store user code.

The last four implemented program memory locations are reserved for the Flash Configuration Words. The reserved addresses are provided in Table 2-2.

Locations, FF0000h and FF0002h, are reserved for the Device ID registers. These bits can be used by the programmer to identify what device type is being programmed. They are described in Section 6.1 “Device ID”. The Device ID registers read out normally, even after code protection is applied.

Figure 2-18 displays the memory map for the PIC24FJXXDA1/DA2/GB2/GA3/GC0 family variants.

3.0 DEVICE PROGRAMMING – ICSP

ICSP mode is a special programming protocol that allows you to read and write to the memory of PIC24FJXXXDA1/DA2/GB2/GA3/GC0 devices. The ICSP mode is the most direct method used to program the device; however, Enhanced ICSP is faster. ICSP mode also has the ability to read the contents of executive memory to determine if the Programming Executive is present. This capability is accomplished by applying control codes and instructions, serially to the device, using pins, PGECx and PGEDx.

In ICSP mode, the system clock is taken from the PGECx pin, regardless of the device's Oscillator Configuration bits. All instructions are shifted serially into an internal buffer, then loaded into the Instruction Register (IR) and executed. No program fetching occurs from internal memory. Instructions are fed in 24 bits at a time. PGEDx is used to shift data in and PGECx is used as both the serial shift clock and the CPU execution clock.

Note: During ICSP operation, the operating frequency of PGECx must not exceed 10 MHz.

3.1 Overview of the Programming Process

See Figure 3-1 for a high-level overview of the programming process. After entering ICSP mode, the first action is to Chip Erase the device. Next, the code memory is programmed, followed by the device Configuration registers. Code memory (including the Configuration registers) is then verified to ensure that programming was successful. Then, the code-protect Configuration bits are programmed, if required.

3.2 ICSP Operation

Upon entry into ICSP mode, the CPU is Idle. Execution of the CPU is governed by an internal state machine. A 4-bit control code is clocked in using PGECx and PGEDx, and this control code is used to command the CPU (see Table 3-1).

The SIX control code is used to send instructions to the CPU for execution and the REGOUT control code is used to read data out of the device via the VISI register.

FIGURE 3-1: HIGH-LEVEL ICSP™ PROGRAMMING FLOW
3.2.1 SIX SERIAL INSTRUCTION EXECUTION

The SIX control code allows execution of PIC24F family assembly instructions. When the SIX code is received, the CPU is suspended for 24 clock cycles, as the instruction is then clocked into the internal buffer. Once the instruction is shifted in, the state machine allows it to be executed over the next four PGECx clock cycles. While the received instruction is executed, the state machine simultaneously shifts in the next 4-bit command (see Figure 3-2).

Coming out of Reset, the first 4-bit control code is always forced to SIX and a forced NOP instruction is executed by the CPU. Five additional PGECx clocks are needed on start-up, resulting in a 9-bit SIX command instead of the normal 4-bit SIX command.

After the forced SIX is clocked in, ICSP operation resumes as normal. That is, the next 24 clock cycles load the first instruction word to the CPU.

Note: To account for this forced NOP, all example code in this specification begins with a NOP to ensure that no data is lost.

FIGURE 3-2: SIX SERIAL EXECUTION

3.2.1.1 Differences Between the Execution of SIX and Normal Instructions

There are some important differences between executing instructions normally and using the SIX ICSP command. Therefore, the code examples in this specification may not match those for performing the same functions during normal device operation.

During SIX ICSP operation:
- Two-word instructions require two SIX operations to clock in all of the necessary data. Examples of two-word instructions are GOTO and CALL.
- Two-cycle instructions require two SIX operations. The first SIX operation shifts in the instruction and begins to execute it. The second SIX operation, which should shift in a NOP to avoid losing data, provides the CPU clocks required to finish executing the instruction. Examples of two-cycle instructions are Table Read and Table Write instructions.
- The CPU does not automatically stall to account for pipeline changes. A CPU stall occurs when an instruction modifies a register that is used for Indirect Addressing by the following instruction.

During normal device operation:
- The CPU will automatically force a NOP while the new data is read. When using ICSP, there is no automatic stall, so any indirect references to a recently modified register should be preceded by a NOP.

For example, the instructions, MOV #0x0,W0 and MOV [W0],W1, must have a NOP inserted among them.

If a two-cycle instruction modifies a register that is used indirectly, it will require two NOPs: one to execute the second half of the instruction and the other to stall the CPU to correct the pipeline.

Instructions, such as TBLWTL [W0++],[W1], should be followed by two NOPs.

- The device Program Counter (PC) continues to automatically increment during ICSP instruction execution, even though the Flash memory is not being used.

As a result, the PC may be incremented to point to invalid memory locations. Invalid memory spaces include unimplemented Flash addresses and the vector space (locations: 0x0 to 0x1FF).

If the PC points to these locations, the device will reset, possibly interrupting the ICSP operation. To prevent this, instructions should be periodically executed to reset the PC to a safe space. The optimal method to accomplish this is to perform a GOTO 0x200.
3.2.2 REGOUT SERIAL INSTRUCTION EXECUTION

The REGOUT control code allows for data to be extracted from the device in ICSP mode. It is used to clock the contents of the VISI register, out of the device, over the PGEDx pin. After the REGOUT control code is received, the CPU is held Idle for 8 cycles. After these 8 cycles, an additional 16 cycles are required to clock the data out (see Figure 3-3).

The REGOUT code is unique because the PGEDx pin is an input when the control code is transmitted to the device. However, after the control code is processed, the PGEDx pin becomes an output as the VISI register is shifted out.

Note 1: After the contents of VISI are shifted out, the PIC24FJXXDA1/DA2/GB2/GA3/GC0 devices maintain PGEDx as an output until the first rising edge of the next clock is received.

2: Data changes on the falling edge and latches on the rising edge of PGECx. For all data transmissions, the Least Significant bit (LSb) is transmitted first.

FIGURE 3-3: REGOUT SERIAL EXECUTION

3.3 Entering ICSP Mode

As displayed in Figure 3-4, entering ICSP Program/Verify mode requires three steps:

1. MCLR is briefly driven high, then low.
2. A 32-bit key sequence is clocked into PGEDx.
3. MCLR is then driven high within a specified period and held.

The programming voltage applied to MCLR is VIH, which is essentially VDD in the case of PIC24FJXXXDA1/DA2/GB2/GA3/GC0 devices. There is no minimum time requirement for holding at VIH. After VIH is removed, an interval of at least P18 must elapse before presenting the key sequence on PGEDx.

The key sequence is a specific 32-bit pattern: ‘0100 1101 0100 0011 0100 1000 0101 0001’ (more easily remembered as 4D434851h in hexadecimal). The device will enter Program/Verify mode only if the sequence is valid. The Most Significant bit (MSb) of the most significant nibble must be shifted in first.

Once the key sequence is complete, VIH must be applied to MCLR and held at that level for as long as Program/Verify mode is to be maintained. An interval of at least time, P19 and P7, must elapse before presenting data on PGEDx. Signals appearing on PGECx, before P7 has elapsed, will not be interpreted as valid.

On successful entry, the program memory can be accessed and programmed in serial fashion. While in ICSP mode, all unused I/Os are placed in the high-impedance state.

FIGURE 3-4: ENTERING ICSP™ MODE

[Diagram showing the entering ICSP mode process with key sequence and timing details.]
3.4 Flash Memory Programming in ICSP Mode

3.4.1 PROGRAMMING OPERATIONS

Flash memory write and erase operations are controlled by the NVMCON register. Programming is performed by setting NVMCON to select the type of erase operation (see Table 3-2) or write operation (see Table 3-3) and initiating the programming by setting the WR control bit (NVMCON<15>).

In ICSP mode, all programming operations are self-timed. There is an internal delay between the user setting the WR control bit and the automatic clearing of the WR control bit when the programming operation is complete. Refer to Section 7.0 “AC/DC Characteristics and Timing Requirements” for information about the delays associated with various programming operations.

</tr>
</tbody>
</table>

3.4.2 STARTING AND STOPPING A PROGRAMMING CYCLE

The WR bit (NVMCON<15>) is used to start an erase or write cycle. Setting the WR bit initiates the programming cycle.

All erase and write cycles are self-timed. The WR bit should be polled to determine if the erase or write cycle has been completed. Starting a programming cycle is performed as follows:

```
BSET NVMCON, #WR
```

3.5 Erasing Program Memory

The procedure for erasing program memory (all of the code memory, data memory, executive memory and code-protect bits) consists of setting NVMCON to 404Fh and executing the programming cycle.

A Chip Erase can erase all of the user memory or all of both the user and configuration memory. A Table Write instruction should be executed prior to performing the Chip Erase to select which sections are erased.

The Table Write instruction is executed:

- If the TBLPAG register points to user space (is less than 0x80), the Chip Erase will erase only user memory and Flash Configuration Words.
- If the TBLPAG register points to configuration space (is greater than or equal to 0x80), the Chip Erase is not allowed. The configuration space can be erased, one page at a time.

**Note:** The Chip Erase is not allowed when the TBLPAG points to the configuration space to avoid the Diagnostic and Calibration Words from getting erased.

**Note:** Program memory must be erased before writing any data to program memory.

3.6 Writing Code Memory

The procedure for writing code memory is the same as that of writing the Configuration registers, except that 64 instruction words are programmed at a time. To facilitate this operation, working registers, W0:W5, are used as temporary holding registers for the data to be programmed.

Table 3-5 provides the ICSP programming details, including the serial pattern with the ICSP command code, which must be transmitted, LSb first, using the PGECx and PGEDx pins (see Figure 3-2).

In Step 1, the Reset vector is exited. In Step 2, the NVMCON register is initialized for programming a full row of code memory. In Step 3, the 24-bit starting destination address for programming is loaded into the TBLPAG register and W7 register. (The upper byte of the starting destination address is stored in TBLPAG and the lower 16 bits of the destination address are stored in W7.)

To minimize the programming time, a packed instruction format is used (see Figure 3-6).

In Step 4, four packed instruction words are stored in working registers, W0:W5, using the MOV instruction and the Read Pointer, W6, is initialized. The contents of W0:W5 (holding the packed instruction word data) are displayed in Figure 3-6.

In Step 5, eight TBLWT instructions are used to copy the data from W0:W5 to the write latches of code memory. Since code memory is programmed, 64 instruction words at a time, Steps 4 and 5 are repeated 16 times to load all the write latches (Step 6).

After the write latches are loaded, programming is initiated by writing to the NVMCON register in Steps 7 and 8. In Step 9, the internal PC is reset to 200h. This is a precautionary measure to prevent the PC from incrementing into unimplemented memory when large devices are being programmed. Lastly, in Step 10, Steps 3-9 are repeated until all of the code memory is programmed.

3.7 Writing Configuration Words

Device configuration for PIC24FJXXXDA1/DA2/GB2/GA3/GC0 devices is stored in Flash Configuration Words at the end of the user space program memory and in multiple register Configuration Words, located in the test space. These registers reflect values read at any Reset from program memory locations. The values for the Configuration Words for the default device configurations are listed in Table 3-6.

The values can be changed only by programming the content of the corresponding Flash Configuration Word and resetting the device. The Reset forces an automatic reload of the Flash stored configuration values by sequencing through the dedicated Flash Configuration Words and transferring the data into the Configuration registers.

For the PIC24FJXXXDA1/DA2/GB2/GA3/GC0 families, certain reserved Configuration bits have default states that must always be maintained to ensure device functionality, regardless of the settings of other Configuration bits. Some of these bits occur in all device families covered by this specification, while others occur only in specific device families. These bits and their values are listed in Table 3-7.

To change the values of the Flash Configuration Word, once it has been programmed, the device must be Chip Erased, as described in Section 3.5 “Erasing Program Memory” and reprogrammed to the desired value. It is not possible to program a ‘0’ to ‘1’; they may be programmed from a ‘1’ to ‘0’ to enable code protection.

Table 3-8 provides the ICSP programming details for programming the Configuration Word locations. This includes the serial pattern with the ICSP command code, which must be transmitted, LSb first, using the PGEIx and PGEDx pins (see Figure 3-2).

In Step 1, the Reset vector is exited. In Step 2, the lower 16 bits of the source address are stored in W7. In Step 3, the NVMCON register is initialized for programming of code memory. In Step 4, the upper byte of the 24-bit starting source address for writing is loaded into the TBLPAG register.

The TBLPAG register must be loaded with 00h for 64 Kbytes, 01h for 128 Kbytes and 256-Kbyte devices.

To verify the data by reading the Configuration Words after performing the write in order, the code protection bits should initially be programmed to a ‘1’ to ensure that the verification can be performed properly. After verification is finished, the code protection bit can be programmed to a ‘0’ by using a word write to the appropriate Configuration Word.

### TABLE 3-6: DEFAULT CONFIGURATION REGISTER VALUES

<table>

3.8 Reading Code Memory

Reading from code memory is performed by executing a series of \texttt{TBLRD} instructions and clocking out the data using the \texttt{REGOUT} command.

Table 3-9 provides the ICSP programming details for reading code memory. In Step 1, the Reset vector is exited. In Step 2, the Write Pointer, W7, is initialized. In Step 3, the 24-bit starting source address for reading is loaded into the TBLPAG register and W6 register. The upper byte of the starting source address is stored in TBLPAG and the lower 16 bits of the source address are stored in W6.

To minimize the reading time, the packed instruction word format that was utilized for writing is also used for reading (see Figure 3-6). In Step 4, two instruction words are read from code memory and clocked out of the device, through the VISI register, using the \texttt{REGOUT} command. Step 4 is repeated until the desired amount of code memory is read.

3.9 Reading Configuration Words

The procedure for reading configuration memory is similar to the procedure for reading code memory, except that 16-bit data words are read instead of 24-bit words. Configuration Words are read, one register at a time.

Table 3-10 provides the ICSP programming details for reading the Configuration Words. Note that the TBLPAG register must be loaded with 00h for 64 Kbytes, 01h for 128 Kbytes and 256-Kbyte devices. W6 is initialized to the lower 16 bits of the Configuration Word location.

3.10 Verify Code Memory and Configuration Code Word

The verify step involves reading back the code memory space, and comparing it with the copy held in the programmer’s buffer. The Configuration registers are verified with the rest of the code.

The flowchart in Figure 3-8 illustrates the verify process. Memory reads occur a single byte at a time, so two bytes must be read to compare with the word in the programmer’s buffer. Refer to Section 3.8 “Reading Code Memory” for implementation details of reading code memory.

Note: Because the Configuration registers include the device code protection bit, code memory should be verified immediately after writing if code protection is enabled. This is because the device will not be readable or verifiable if a device Reset occurs after the code-protect bit in CW1 has been cleared.

3.11 Reading the Application ID Word

The Application ID Word is stored at address, 8007F0h, in executive code memory. To read this memory location, you must use the SIX control code to move this program memory location to the VISI register. Then, the REGOUT control code must be used to clock the contents of the VISI register out of the device. Table 3-11 provides the corresponding control and instruction codes that must be serially transmitted to the device to perform this operation.

After the programmer has clocked out the Application ID Word, it must be inspected. If the Application ID has the value, CCh, the Programming Executive is resident in memory and the device can be programmed using the mechanism described in Section 4.0 “Device Programming – Enhanced ICSP”. However, if the Application ID has any other value, the Programming Executive is not resident in memory; it must be loaded to memory before the device can be programmed. The procedure for loading the Programming Executive to memory is described in Section 5.4 “Programming the Programming Executive to Memory”.

3.12 Exiting ICSP Mode

Exiting Program/Verify mode is done by removing VIH from MCLR, as displayed in Figure 3-9. The only requirement for exit is that an interval, P16, should elapse between the last clock and program signals on PGECx and PGEDx before removing VIH.

4.0 DEVICE PROGRAMMING – ENHANCED ICSP

This section discusses programming the device through Enhanced ICSP and the Programming Executive. The Programming Executive resides in executive memory (separate from code memory) and is executed when Enhanced ICSP Programming mode is entered. The Programming Executive provides the mechanism for the programmer (host device) to program and verify the PIC24FJXXXDA1/DA2/GB2/GA3/GC0 devices, using a simple command set and communication protocol. There are several basic functions provided by the Programming Executive:

• Read Memory
• Erase Memory
• Program Memory
• Blank Check
• Read Executive Firmware Revision

The Programming Executive performs the low-level tasks required for erasing, programming and verifying a device. This allows the programmer to program the device by issuing the appropriate commands and data. Table 4-1 provides the commands. A detailed description for each command is provided in Section 5.2 “Programming Executive Commands”.

<table>
<thead>
<tr>

<td>Program One Word of Code Memory and Verify</td>
</tr>
<tr>
<td>QBLANK</td>
<td>Query if the Code Memory is Blank</td>
</tr>
<tr>
<td>QVER</td>
<td>Query the Software Version</td>
</tr>
</tbody>
</table>

The Programming Executive uses the device’s data RAM for variable storage and program execution. After the Programming Executive has run, no assumptions should be made about the contents of data RAM.

4.1 Overview of the Programming Process

Figure 4-1 displays the high-level overview of the programming process. After entering Enhanced ICSP mode, the Programming Executive is verified. Next, the device is erased. Then, the code memory is programmed, followed by the configuration locations. Code memory (including the Configuration registers) is then verified to ensure that programming was successful.

After the Programming Executive has been verified in memory (or loaded if not present), the PIC24FJXXXDA1/DA2/GB2/GA3/GC0 families can be programmed using the command set provided in Table 4-1.

4.2 Confirming the Presence of the Programming Executive

Before programming can begin, the programmer must confirm that the Programming Executive is stored in executive memory. The procedure for this task is displayed in Figure 4-2.

First, ICSP mode is entered. Then, the unique Application ID Word, stored in executive memory, is read. If the Programming Executive is resident, the Application ID Word is CCh, which means programming can resume as normal. However, if the Application ID Word is not CCh, the Programming Executive must be programmed to executive code memory using the method described in Section 5.4 “Programming the Programming Executive to Memory”.

Section 3.0 “Device Programming – ICSP” describes the ICSP programming method. Section 3.11 “Reading the Application ID Word” describes the procedure for reading the Application ID Word in ICSP mode.
4.3 Entering Enhanced ICSP Mode

As displayed in Figure 4-3, entering Enhanced ICSP Program/Verify mode requires three steps:

1. The MCLR pin is briefly driven high, then low.
2. A 32-bit key sequence is clocked into PGEDx.
3. MCLR is then driven high within a specified period and held.

The programming voltage applied to MCLR is $V_{IH}$, which is essentially $V_{DD}$ in the case of PIC24FJXXXDA1/DA2/GB2/GA3/GC0 devices. There is no minimum time requirement for holding at $V_{IH}$. After $V_{IH}$ is removed, an interval of at least P18 must elapse before presenting the key sequence on PGEDx.

The key sequence is a specific 32-bit pattern: '0100 1101 0100 0011 0100 1000 0101 0000' (more easily remembered as 4D434850h in hexadecimal format). The device will enter Program/Verify mode only if the key sequence is valid. The MSb of the most significant nibble must be shifted in first.

Once the key sequence is complete, $V_{IH}$ must be applied to MCLR and held at that level for as long as Program/Verify mode is to be maintained. An interval of at least time, P19 and P7, must elapse before presenting data on PGEDx. Signals appearing on PGEDx, before P7 has elapsed, will not be interpreted as valid.

On successful entry, the program memory can be accessed and programmed in serial fashion. While in the Program/Verify mode, all unused I/Os are placed in the high-impedance state.
4.4 Blank Check

The term, “Blank Check”, implies verifying that the device has been successfully erased and has no programmed memory locations. A blank or erased memory location is always read as ‘1’.

The Device ID registers (FF0002h:FF0000h) can be ignored by the Blank Check since this region stores device information that cannot be erased. The device Configuration registers are also ignored by the Blank Check. Additionally, all unimplemented memory space should be ignored by the Blank Check.

The QBLANK command is used for the Blank Check. It determines if the code memory is erased by testing these memory regions. A ‘BLANK’ or ‘NOT BLANK’ response is returned. If it is determined that the device is not blank, it must be erased before attempting to program the chip.

4.5 Code Memory Programming

4.5.1 PROGRAMMING METHODOLOGY

Code memory is programmed with the PROGP command. PROGP programs one row of code memory starting from the memory address specified in the command. The number of PROGP commands required to program a device depends on the number of write blocks that must be programmed in the device.

A flowchart for programming the code memory of the PIC24FJXXXXDA1/DA2/GB2/GA3/GC0 families is displayed in Figure 4-4. In this example, all 87K instruction words of a 256-Kbyte device are programmed. First, the number of commands to send (called ‘RemainingCmds’ in the flowchart) is set to 1368 and the destination address (called ‘BaseAddress’) is set to ‘0’. Next, one write block in the device is programmed with a PROGP command. Each PROGP command contains data for one row of code memory of the device. After the first command is processed successfully, ‘RemainingCmds’ is decremented by 1 and compared with 0. Since there are more PROGP commands to send, ‘BaseAddress’ is incremented by 80h to point to the next row of memory.

On the second PROGP command, the second row is programmed. This process is repeated until the entire device is programmed. No special handling must be performed when a panel boundary is crossed.

4.5.2 PROGRAMMING VERIFICATION

After code memory is programmed, the contents of memory can be verified to ensure that programming was successful. Verification requires code memory to be read back and compared with the copy held in the programmer’s buffer.

The READP command can be used to read back all of the programmed code memory. Alternatively, you can have the programmer perform the verification, after the entire device is programmed, using a checksum computation.

4.6 Configuration Bits Programming

4.6.1 OVERVIEW

The PIC24FJXXXDA1/DA2/GB2/GA3/GC0 families have Configuration bits stored in the last four locations of implemented program memory (see Table 2-2 for locations). These bits can be set or cleared to select various device configurations.

There are two types of Configuration bits: system operation bits and code-protect bits. The system operation bits determine the power-on settings for system level components, such as the oscillator and Watchdog Timer. The code-protect bits prevent program memory from being read and written to.

The tables on the following pages provide the Configuration bit descriptions and their locations within the Flash Configuration Words:
- Table 4-2, PIC24FJXXXDA1/DA2/GB2 families
- Table 4-3, PIC24FJXXG3 family
- Table 4-4, PIC24FJXXXG0 family.

Note: Although not implemented with a specific function, some Configuration bit positions have default states that must always be maintained to ensure device functionality, regardless of the settings of other Configuration bits. Refer to Table 3-7 for a list of these bit positions and their default states.

| DSBOREN | CW4<6> | Deep Sleep BOR Enable bit
1 = BOR is enabled in Deep Sleep
0 = BOR is disabled in Deep Sleep (does not affect Sleep mode) |
| DSWDTOSC | CW4<5> | DSWDT Reference Clock Select bit
1 = DSWDT uses LPRC as reference clock
0 = DSWDT uses SOSC as reference clock |

**Note 1:** Bits<23:16> should be programmed to a value of 0x00 to ensure that accidental program execution of any of the Configuration Words would be interpreted as a NOP opcode.

2: Voltage reference selection is not available on 64-pin devices. These positions must always be programmed (= 0) on these devices.

3: Implemented on 100-pin and 121-pin devices only. This bit position must be ‘1’ on 64-pin and 80-pin devices.

4: The JTAGEN bit can be modified only using In-Circuit Serial Programming™ (ICSP™).

5: Irrespective of the WPCFG status, if WPEND = 1 or if WPFP corresponds to the Configuration Words page, the Configuration Words page will be protected.

4.6.2 PROGRAMMING METHODOLOGY

Configuration bits may be programmed, a single word at a time, using the PROGW command. This command specifies the configuration data and Configuration register address. When Configuration bits are programmed, any unimplemented or reserved bits must be programmed with a '1'.

Four PROGW commands are required to program the Configuration bits. See Figure 4-5 for a flowchart for Configuration bit programming.

Note: If the General Segment Code-Protect bit (GCP) is programmed to '0', code memory is code-protected and cannot be read. Code memory must be verified before enabling read protection. See Section 4.6.4 “Code-Protect Configuration Bits” for more information about code-protected Configuration bits.

4.6.3 PROGRAMMING VERIFICATION

After the Configuration bits are programmed, the contents of memory should be verified to ensure that the programming was successful. Verification requires the Configuration bits to be read back and compared with the copy held in the programmer’s buffer. The READP command reads back the programmed Configuration bits and verifies that the programming was successful.

FIGURE 4-5: CONFIGURATION BIT PROGRAMMING FLOW

Note 1: Refer to Table 2-2 for Flash Configuration Word addresses.
4.6.4 CODE-PROTECT CONFIGURATION BITS

PIC24FJXXXDA1/DA2/GB2/GA3/GC0 family devices provide two complimentary methods to protect application code from overwrites and erasures. These also help to protect the device from inadvertent configuration changes during run time. Additional information is available in the product data sheet.

4.6.4.1 GENERAL SEGMENT PROTECTION

For all devices in the PIC24FJXXXDA1/DA2/GB2/GA3/GC0 families, the on-chip program memory space is treated as a single block, known as the General Segment (GS). Code protection for this block is controlled by one Configuration bit, GCP. This bit inhibits external reads and writes to the program memory space; it has no direct effect in normal execution mode.

Write protection is controlled by the GWRP bit in the Configuration Word. When GWRP is programmed to ‘0’, internal write and erase operations to the program memory are blocked.

4.6.4.2 CODE SEGMENT PROTECTION

In addition to global General Segment protection, a separate subrange of the program memory space can be individually protected against writes and erases. This area can be used for many purposes where a separate block of write and erase-protected code is needed, such as bootloader applications. Unlike common boot block implementations, the specially protected segment in PIC24FJXXXDA1/DA2/GB2/GA3/GC0 devices can be located by the user anywhere in the program space, and configured in a wide range of sizes.

Code segment protection provides an added level of protection to a designated area of program memory by disabling the NVM safety interlock, whenever a write or erase address falls, within a specified range. It does not override General Segment protection controlled by the GCP or GWRP bits. For example, if GCP and GWRP are enabled, enabling segmented code protection for the bottom half of program memory does not undo General Segment protection for the top half.

Note: Chip Erasing in ICSP mode is the only way to reprogram code-protect bits from an ON state (‘0’) to an OFF state (‘1’).

4.7 Exiting Enhanced ICSP Mode

Exiting Program/Verify mode is done by removing Vih from MCLR, as displayed in Figure 4-6. The only requirement for exit is that an interval, P16, should elapse between the last clock, and program signals on PGECx and PGEDx, before removing Vih.

FIGURE 4-6: EXITING ENHANCED ICSP™ MODE

Note:
5.0 THE PROGRAMMING EXECUTIVE

Note: The Programming Executive (PE) can be located within the following folder within your installation of MPLAB® IDE: Microchip\MPLAB IDE\REAL ICE and then select the Hex PE file: RIPE_01c_xxxxxx.hex.

5.1 Programming Executive Communication

The programmer and Programming Executive have a master-slave relationship, where the programmer is the master programming device and the Programming Executive is the slave.

All communication is initiated by the programmer in the form of a command. Only one command at a time can be sent to the Programming Executive. In turn, the Programming Executive only sends one response to the programmer after receiving and processing a command. The Programming Executive command set is described in Section 5.2 “Programming Executive Commands”. The response set is described in Section 5.3 “Programming Executive Responses”.

5.1.1 COMMUNICATION INTERFACE AND PROTOCOL

The Enhanced ICSP interface is a 2-wire SPI, implemented using the PGECx and PGEDx pins. The PGECx pin is used as a clock input pin and the clock source must be provided by the programmer. The PGEDx pin is used for sending command data to, and receiving response data from, the Programming Executive.

Data transmits to the device must change on the rising edge and hold on the falling edge. Data receives from the device must change on the falling edge and hold on the rising edge.

All data transmissions are sent, MSb first, using 16-bit mode (see Figure 5-1).

FIGURE 5-1: PROGRAMMING EXECUTIVE SERIAL TIMING FOR DATA RECEIVED FROM DEVICE

Since a 2-wire SPI is used, and data transmissions are half-duplex, a simple protocol is used to control the direction of PGEDx. When the programmer completes a command transmission, it releases the PGEDx line and allows the Programming Executive to drive this line high. The Programming Executive keeps the PGEDx line high to indicate that it is processing the command.

After the Programming Executive has processed the command, it brings PGEDx low for 15 \( \mu s \) to indicate to the programmer that the response is available to be clocked out. The programmer can begin to clock out the response, 23 \( \mu s \) after PGEDx is brought low, and it must provide the necessary amount of clock pulses to receive the entire response from the Programming Executive.

After the entire response is clocked out, the programmer should terminate the clock on PGECx until it is time to send another command to the Programming Executive. See Figure 5-3 for this protocol.

5.1.2 SPI RATE

In Enhanced ICSP mode, the PIC24FJXXXDA1/DA2/GB2/GA3/GC0 devices operate from the Internal Fast RC Oscillator (FRCDIV), which has a nominal frequency of 8 MHz. This oscillator frequency yields an effective system clock frequency of 4 MHz. To ensure that the programmer does not clock too fast, it is recommended that a 4 MHz clock be provided by the programmer.

FIGURE 5-2: PROGRAMMING EXECUTIVE SERIAL TIMING FOR DATA TRANSMITTED TO DEVICE
5.1.3 TIME-OUTS
The Programming Executive uses no Watchdog Timer or time-out for transmitting responses to the programmer. If the programmer does not follow the flow control mechanism using PGECx, as described in Section 5.1.1 “Communication Interface and Protocol”, it is possible that the Programming Executive will behave unexpectedly while trying to send a response to the programmer. Since the Programming Executive has no time-out, it is imperative that the programmer correctly follow the described communication protocol. As a safety measure, the programmer should use the command time-outs identified and provided in Table 5-1. If the command time-out expires, the programmer should reset the Programming Executive and start programming the device again.

FIGURE 5-3: PROGRAMMING EXECUTIVE – PROGRAMMER COMMUNICATION PROTOCOL

5.2 Programming Executive Commands
The Programming Executive command set is provided in Table 5-1. This table contains the opcode, mnemonic, length, time-out and description for each command. Functional details on each command are provided in Section 5.2.4 “Command Descriptions”.

5.2.1 COMMAND FORMAT
All Programming Executive commands have a general format, consisting of a 16-bit header and any required data for the command (see Figure 5-4). The 16-bit header consists of a 4-bit opcode field, which is used to identify the command, followed by a 12-bit command length field.

FIGURE 5-4: COMMAND FORMAT

<table>
<thead>
<tr>
<th>15</th>
<th>12</th>
<th>11</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Opcode</td>
<td>Length</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Command Data First Word (if required)</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Command Data Last Word (if required)</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The command opcode must match one of those in the command set. Any command that is received, which does not match the list in Table 5-1, will return a “NACK” response (see Section 5.3.1.1 “Opcode Field”).

The command length is represented in 16-bit words since the SPI operates in 16-bit mode. The Programming Executive uses the command length field to determine the number of words to read from the SPI port. If the value of this field is incorrect, the command will not be properly received by the Programming Executive.
5.2.2 PACKED DATA FORMAT

When 24-bit instruction words are transferred across the 16-bit SPI interface, they are packed to conserve space using the format displayed in Figure 5-5. This format minimizes traffic over the SPI and provides the Programming Executive with data that is properly aligned for performing Table Write operations.

FIGURE 5-5: PACKED INSTRUCTION WORD FORMAT

<table>
<thead>
<tr>
<th>15</th>
<th>8</th>
<th>7</th>
<th>0</th>

</tbody>
</table>

Table 2-2: Pack Word Format

| LSWx: Least Significant 16 bits of instruction word | MSBx: Most Significant Bytes of instruction word |

Note: When the number of instruction words transferred is odd, MSB2 is zero and LSW2 cannot be transmitted.

5.2.3 PROGRAMMING EXECUTIVE ERROR HANDLING

The Programming Executive will “NACK” all unsupported commands. Additionally, due to the memory constraints of the Programming Executive, no checking is performed on the data contained in the programmer command. It is the responsibility of the programmer to command the Programming Executive with valid command arguments or the programming operation may fail. Additional information on error handling is provided in Section 5.3.1.3 “QE_Code Field”.

</tbody>
</table>

Note 1: One row of code memory consists of (64) 24-bit words. Refer to Table 2-2 for device-specific information.
5.2.4 COMMAND DESCRIPTIONS

All commands supported by the Programming Executive are described in Section 5.2.5 “SCHECK Command” through Section 5.2.12 “QVER Command”.

5.2.5 SCHECK COMMAND

The SCHECK command instructs the Programming Executive to do nothing but generate a response. This command is used as a “Sanity Check” to verify that the Programming Executive is operational.

**Expected Response (2 words):**

1000h
0002h

**Note:** This instruction is not required for programming; it is provided for development purposes only.

5.2.6 READC COMMAND

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Opcode</td>
<td>0h</td>
</tr>
<tr>
<td>Length</td>
<td>1h</td>
</tr>
</tbody>
</table>

The READC command instructs the Programming Executive to read N or Device ID registers, starting from the 24-bit address specified by Addr_MSB and Addr_LS. This command can only be used to read 8-bit or 16-bit data.

When this command is used to read Device ID registers, the upper byte in every data word returned by the Programming Executive is 00h and the lower byte contains the Device ID register value.

**Expected Response (4 + 3 * (N – 1)/2 words for N odd):**

1100h
2 + N
Device ID Register 1
...
Device ID Register N

**Note:** Reading unimplemented memory will cause the Programming Executive to reset. Ensure that only memory locations present on a particular device are accessed.
5.2.7 READP COMMAND

The READP command instructs the Programming Executive to read N 24-bit words of code memory, including Configuration Words, starting from the 24-bit address specified by Addr_MSB and Addr_LS. This command can only be used to read 24-bit data. All data returned in response to this command uses the packed data format described in Section 5.2.2 “Packed Data Format”.

**Expected Response (2 + 3 * N/2 Words for N Even):**

1200h
2 + 3 * N/2
Least Significant Program Memory Word 1
...
Least Significant Data Word N

**Expected Response (4 + 3 * (N – 1)/2 Words for N Odd):**

1200h
4 + 3 * (N – 1)/2
Least Significant Program Memory Word 1
...
MSB of Program Memory Word N (zero-padded)

**Note:** Reading unimplemented memory will cause the Programming Executive to reset. Ensure that only memory locations present on a particular device are accessed.

<table>
<thead>
<tr>

<tr>
<td>Addr_MSB</td>
<td>MSB of 24-bit source address</td>
</tr>
<tr>
<td>Addr_LS</td>
<td>Least Significant 16 bits of 24-bit source address</td>
</tr>
</tbody>
</table>

5.2.8 PROGC COMMAND

The PROGC command instructs the Programming Executive to program a single Device ID register located at the specified memory address. After the specified data word has been programmed to code memory, the Programming Executive verifies the programmed data against the data in the command.

**Expected Response (2 Words):**

1400h
0002h

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Opcode</td>
<td>4h</td>
</tr>
<tr>

<td>0h</td>
</tr>
<tr>
<td>Addr_MSB</td>
<td>MSB of the 24-bit destination address</td>
</tr>
<tr>
<td>Addr_LS</td>
<td>Least Significant 16 bits of the 24-bit destination address</td>
</tr>
<tr>
<td>Data</td>
<td>8-bit data word</td>
</tr>
</tbody>
</table>
5.2.9 PROGP COMMAND

The PROGP command instructs the Programming Executive to program one row of code memory, including Configuration Words (64 instruction words), to the specified memory address. Programming begins with the row address specified in the command. The destination address should be a multiple of 80h.

The data to program to memory, located in command words, D_1 through D_96, must be arranged using the packed instruction word format displayed in Figure 5-5.

After all data has been arranged, the Programming Executive verifies the programmed data against the data in the command.

**Expected Response (2 Words):**

1500h
0002h

**Note:** Refer to Table 2-2 for code memory size information.

5.2.10 PROGW COMMAND

The PROGW command instructs the Programming Executive to program one word of code memory (3 bytes) to the specific memory address.

After the word has been programmed to code memory, the Programming Executive verifies the programmed data against the data in the command.

**Expected Response (2 words):**

1600h
0002h
5.2.11 QBLANK COMMAND

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Opcode</td>
<td>Ah</td>
</tr>
<tr>
<td>Length</td>
<td>3h</td>
</tr>
<tr>
<td>PSize</td>
<td>Length of program memory to check in 24-bit words plus one (max. of 49152)</td>
</tr>
</tbody>
</table>

The QBLANK command queries the Programming Executive to determine if the contents of code memory and code-protect Configuration bits (GCP and GWRP) are blank (contain all ‘1’s). The size of code memory to check must be specified in the command.

The Blank Check for code memory begins at 0h and advances toward larger addresses for the specified number of instruction words.

QBLANK returns a QE_Code of F0h if the specified code memory and code-protect bits are blank; otherwise, QBLANK returns a QE_Code of 0Fh.

**Expected Response (2 Words for Blank Device):**

```
1AF0h
0002h
```

**Expected Response (2 Words for non-Blank device):**

```
1A0Fh
0002h
```

**Note:** QBLANK does not check the system operation Configuration bits, since these bits are not set to ‘1’ when a Chip Erase is performed.

5.2.12 QVER COMMAND

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Opcode</td>
<td>Bh</td>
</tr>
<tr>
<td>Length</td>
<td>1h</td>
</tr>
</tbody>
</table>

The QVER command queries the version of the Programming Executive software stored in test memory. The “version.revision” information is returned in the response’s QE_Code using a single byte with the following format: main version in upper nibble and revision in the lower nibble (i.e., 23h means Version 2.3 of Programming Executive software).

**Expected Response (2 Words):**

```
1BMNh (where “MN” stands for Version M.N)
0002h
```
5.3 Programming Executive Responses

The Programming Executive sends a response to the programmer for each command that it receives. The response indicates if the command was processed correctly. It includes any required response data or error data.

The Programming Executive response set is provided in Table 5-2. This table contains the opcode, mnemonic and description for each response. The response format is described in Section 5.3.1 “Response Format”.

### TABLE 5-2: PROGRAMMING EXECUTIVE RESPONSE OPCODES

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Mnemonic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1h</td>
<td>PASS</td>
<td>Command is successfully processed</td>
</tr>
<tr>
<td>2h</td>
<td>FAIL</td>
<td>Command is unsuccessfully processed</td>
</tr>
<tr>
<td>3h</td>
<td>NACK</td>
<td>Command is not known</td>
</tr>
</tbody>
</table>

5.3.1 RESPONSE FORMAT

All Programming Executive responses have a general format, consisting of a two-word header and any required data for the command.

<table>
<thead>
<tr>
<th>15 12 11 8 7 0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Opcode</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>

5.3.1.1 Opcode Field

The opcode is a 4-bit field in the first word of the response. The opcode indicates how the command was processed (see Table 5-2). If the command was processed successfully, the response opcode is PASS. If there was an error in processing the command, the response opcode is FAIL and the QE_Code indicates the reason for the failure. If the command sent to the Programming Executive is not identified, the Programming Executive returns a NACK response.

5.3.1.2 Last_Cmd Field

The Last_Cmd is a 4-bit field in the first word of the response and indicates the command that the Programming Executive processed. Since the Programming Executive can only process one command at a time, this field is technically not required. However, it can be used to verify that the Programming Executive correctly received the command that the programmer transmitted.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Opcode</td>
<td>Response opcode</td>
</tr>
<tr>
<td>Last_Cmd</td>
<td>Programmer command that generated the response</td>
</tr>
<tr>
<td>QE_Code</td>
<td>Query code or error code</td>
</tr>
<tr>
<td>Length</td>
<td>Response length in 16-bit words (includes 2 header words)</td>
</tr>
<tr>
<td>D_1</td>
<td>First 16-bit data word (if applicable)</td>
</tr>
<tr>
<td>D_N</td>
<td>Last 16-bit data word (if applicable)</td>
</tr>
</tbody>
</table>
5.3.1.3 QE_Code Field
The QE_Code is a byte in the first word of the response. This byte is used to return data for query commands and error codes for all other commands.

When the Programming Executive processes one of the two query commands (QBLANK or QVER), the returned opcode is always PASS and the QE_Code holds the query response data. The format of the QE_Code for both queries is provided in Table 5-3.

TABLE 5-3: QE_Code FOR QUERIES

<table>
<thead>
<tr>
<th>Query</th>
<th>QE_Code</th>
</tr>
</thead>
</table>
| QBLANK| 0Fh = Code memory is NOT blank  
|       | F0h = Code memory is blank       |
| QVER  | 0xMN, where Programming Executive Software Version = M.N (i.e., 32h means Software Version 3.2) |

When the Programming Executive processes any command other than a query, the QE_Code represents an error code. Supported error codes are provided in Table 5-4. If a command is successfully processed, the returned QE_Code is set to 0h, which indicates that there was no error in the command processing. If the verification of the programming for the PROGP or PROGC command fails, the QE_Code is set to 1h. For all other Programming Executive errors, the QE_Code is 2h.

TABLE 5-4: QE_Code FOR NON-QUERY COMMANDS

<table>
<thead>
<tr>
<th>QE_Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0h</td>
<td>No error</td>
</tr>
<tr>
<td>1h</td>
<td>Verify failed</td>
</tr>
<tr>
<td>2h</td>
<td>Other error</td>
</tr>
</tbody>
</table>

5.3.1.4 Response Length
The response length indicates the length of the Programming Executive’s response in 16-bit words. This field includes the 2 words of the response header.

With the exception of the response for the READP command, the length of each response is only 2 words. The response to the READP command uses the packed instruction word format, described in Section 5.2.2 “Packed Data Format”. When reading an odd number of program memory words (N odd), the response to the READP command is (3 * (N + 1)/2 + 2) words. When reading an even number of program memory words (N even), the response to the READP command is (3 * N/2 + 2) words.
5.4 Programming the Programming Executive to Memory

5.4.1 OVERVIEW

If it is determined that the Programming Executive is not present in executive memory (as described in Section 4.2 “Confirming the Presence of the Programming Executive”), it must be programmed into executive memory using ICSP, as described in Section 3.0 “Device Programming – ICSP”.

Storing the Programming Executive to executive memory is similar to normal programming of code memory. Namely, the executive memory must be erased and then the Programming Executive must be programmed, 64 words at a time. Table 5-5 provides this control flow.

Note: The Programming Executive must always be erased before it is programmed, as described in Table 5-5.

<table>

5.4.2 PROGRAMMING VERIFICATION

After the Programming Executive has been programmed to executive memory using ICSP, it must be verified. Verification is performed by reading out the contents of executive memory and comparing it with the image of the Programming Executive stored in the programmer.

Reading the contents of executive memory can be performed using the same technique described in Section 3.8 “Reading Code Memory”.

A procedure for reading executive memory is provided in Table 5-6. Note that in Step 2, the TBLPAG register is set to 80h, such that executive memory may be read. The last eight words of executive memory should be verified with stored values of the Diagnostic and Calibration Words to ensure accuracy.

---

### TABLE 5-5: PROGRAMMING THE PROGRAMMING EXECUTIVE (CONTINUED)

<table>

0000 000000 NOP

0000 000000 NOP

0001 <VISI> Clock out contents of VISI register

0000 000000 NOP

0000 BA0BB6 TBLRDL [W6++], [W7]

0000 000000 NOP

0000 000000 NOP

0001 <VISI> Clock out contents of VISI register

0000 000000 NOP

**Step 5:** Reset the device internal PC.

0000 040200 GOTO 0x200

0000 000000 NOP

**Step 6:** Repeat Steps 4 and 5 until all 1024 instruction words of executive memory are read.
6.0 DEVICE DETAILS

6.1 Device ID

The Device ID region of memory can be used to determine mask, variant and manufacturing information about the chip. The Device ID region is 2 x 16 bits and it can be read using the READC command. This region of memory is read-only and can also be read when code protection is enabled.

Table 6-1 provides the Device ID for each device, Table 6-2 provides the Device ID registers and Table 6-3 lists and describes the bit field of each register.

6.2 Checksum Computation

Checksums for the PIC24FJXXXDA1/DA2/GB2/GA3/GC0 families are 16 bits in size. The checksum is calculated by summing the following:

- Contents of code memory locations
- Contents of Configuration registers

Table 6-4 lists the devices and describes how to calculate the checksum for each device. All memory locations are summed, one byte at a time, using only their native data size. Especially, Configuration registers are summed by adding the lower two bytes of these locations (the upper byte is ignored), while code memory is summed by adding all three bytes of code memory.

APPENDIX A: REVISION HISTORY

Revision A (February 2009)
Initial revision of this document, released for PIC24FJ128DA1/DA2/GB2 family devices.

Revision B (September 2010)
Adds PIC24FJ128GA3 family devices.

Revision C (August 2011)
Adds PIC24FJ128GC0 family devices.

Amends Section 3.7 “Writing Configuration Words” with a comprehensive list of reserved bits with specific programming requirements (Table 3-7). Existing tables in this section are sequentially renumbered from the previous revision.

Updates the following Configuration bits and definitions for PIC24FJ128GA3 family devices (Table 4-3):
• SOSCSEL (redefined as a single bit, CW3<8>)
• ALTVREF (corrected from ALTVREF)

Removes the BBEN, RTCBAT and BBDIS Configuration bits from PIC24FJ128GA3 family devices.

Adds revision history as a new feature.

Revision D (December 2011)
Removes the BORV bit from the Configuration register (CW2<3>) and changes it to reserved.

Revision E (March 2012)
Adds the BOREN1 bit (CW2<3>) to PIC24FJ128GA310 family devices, and describes its operation as part of a pair with the existing BOREN bit.

Removes previous independent description of the BOREN Configuration bit.
Note the following details of the code protection feature on Microchip devices:

- Microchip products meet the specification contained in their particular Microchip Data Sheet.
- Microchip believes that its family of products is one of the most secure families of its kind on the market today, when used in the intended manner and under normal conditions.
- There are dishonest and possibly illegal methods used to breach the code protection feature. All of these methods, to our knowledge, require using the Microchip products in a manner outside the operating specifications contained in Microchip’s Data Sheets. Most likely, the person doing so is engaged in theft of intellectual property.
- Microchip is willing to work with the customer who is concerned about the integrity of their code.
- Neither Microchip nor any other semiconductor manufacturer can guarantee the security of their code. Code protection does not mean that we are guaranteeing the product as “unbreakable.”

Code protection is constantly evolving. We at Microchip are committed to continuously improving the code protection features of our products. Attempts to break Microchip’s code protection feature may be a violation of the Digital Millennium Copyright Act. If such acts allow unauthorized access to your software or other copyrighted work, you may have a right to sue for relief under that Act.
