This document includes the programming specifications for the following devices:

- PIC16F1574 • PIC16LF1574
- PIC16F1575 • PIC16LF1575
- PIC16F1578 • PIC16LF1578
- PIC16F1579 • PIC16LF1579

1.0 OVERVIEW

The device can be programmed using either the high-voltage In-Circuit Serial Programming™ (ICSP™) method or the low-voltage ICSP method.

1.1 Hardware Requirements

1.1.1 HIGH-VOLTAGE ICSP PROGRAMMING

In High-Voltage ICSP mode, the device requires two programmable power supplies: one for VDD and one for the MCLR/VPP pin.

1.1.2 LOW-VOLTAGE ICSP PROGRAMMING

In Low-Voltage ICSP mode, these devices can be programmed using a single VDD source in the operating range. The MCLR/VPP pin does not have to be brought to a different voltage, but can instead be left at the normal operating voltage.

1.1.2.1 Single-Supply ICSP Programming

The LVP bit in Configuration Word 2 enables single-supply (low-voltage) ICSP programming. The LVP bit defaults to a ‘1’ (enabled) from the factory. The LVP bit may only be programmed to ‘0’ by entering the High-Voltage ICSP mode, where the MCLR/VPP pin is raised to VHH. Once the LVP bit is programmed to a ‘0’, only the High-Voltage ICSP mode is available and only the High-Voltage ICSP mode can be used to program the device.

Note 1: The High-Voltage ICSP mode is always available, regardless of the state of the LVP bit, by applying VHH to the MCLR/VPP pin.

2: While in Low-Voltage ICSP mode, MCLR is always enabled, regardless of the MCLRE bit, and the port pin can no longer be used as a general purpose input.

1.2 Pin Utilization

Five pins are needed for ICSP programming. The pins are listed in Table 1-1.

### TABLE 1-1: PROGRAMMING PIN DESCRIPTIONS

<td>Ground</td>
</tr>
</tbody>
</table>

Legend:  I = Input, O = Output, P = Power

Note 1: The programming high voltage is internally generated. To activate the Program/Verify mode, high voltage needs to be applied to MCLR input. Since the MCLR is used for a level source, MCLR does not draw any significant current.

3.1 User ID Location

A user may store identification information (user ID) in four designated locations. The user ID locations are mapped to 8000h-8003h. Each location is 14 bits in length. Code protection has no effect on these memory locations. Each location may be read with code protection enabled or disabled.

Note: MPLAB® IDE only displays the seven Least Significant bits (LSb) of each user ID location; the upper bits are not read. It is recommended that only the seven LSbs be used if MPLAB IDE is the primary tool used to read these addresses.

3.2 Revision ID

The revision ID word is located at 8005h. This location is read-only and cannot be erased or modified.

3.3 Device ID

The device ID word is located at 8006h. This location is read-only and cannot be erased or modified.

3.4 Configuration Words

The device has two Configuration Words, Configuration Word 1 (8007h) and Configuration Word 2 (8008h). The individual bits within these Configuration Words are used to enable or disable device functions such as the Brown-out Reset, code protection and Power-up Timer.

3.5 Calibration Words

The internal calibration values are factory-calibrated and stored in the Calibration Word locations. See Figure 3-1 for address information.

The Calibration Words do not participate in erase operations. The device can be erased without affecting the Calibration Words.

U = Unimplemented bit, read as ‘1’

‘0’ = Bit is cleared
‘1’ = Bit is set
n = Value when blank or after Bulk Erase

| bit 13-12 | Unimplemented: Read as ‘1’ |
| bit 11 | **CLKOUTEN**: Clock Out Enable bit |
| 1 = OFF | CLKOUT function is disabled. I/O or oscillator function on CLKOUT pin |
| 0 = ON | CLKOUT function is enabled on CLKOUT pin |

| bit 10-9 | **BOREN<1:0>**: Brown-out Reset Enable bits(1) |
| 11 = ON | Brown-out Reset enabled. The SBOREN bit is ignored. |
| 10 = SLEEP | Brown-out Reset enabled while running and disabled in Sleep. The SBOREN bit is ignored. |
| 01 = SBODEN | Brown-out Reset controlled by the SBOREN bit in the PCON register |
| 00 = OFF | Brown-out Reset disabled. The SBOREN bit is ignored. |

| bit 8 | Unimplemented: Read as ‘1’ |
| bit 7 | **CP**: Flash Program Memory Code Protection bit(2) |
| 1 = OFF | Code protection off. Program Memory can be read and written. |
| 0 = ON | Code protection on. Program Memory cannot be read or written externally. |

| bit 6 | **MCLRE**: MCLR/VPP Pin Function Select bit |
| if LVP bit = 1 (ON): | This bit is ignored. MCLR/VPP pin function is MCLR; Weak pull-up enabled. |
| if LVP bit = 0 (OFF): | 1 = ON MCLR/VPP pin function is MCLR; Weak pull-up enabled. |
| 0 = OFF MCLR/VPP pin function is digital input; MCLR internally disabled; Weak pull-up under control of pin’s WPU control bit. |

| bit 5 | **PWRTE**: Power-up Timer Enable bit(1) |
| 1 = OFF | PWRT disabled |
| 0 = ON | PWRT enabled |

| bit 4-3 | **WDTE<1:0>**: Watchdog Timer Enable bit |
| 11 = ON | WDT enabled. SWDTEN is ignored. |
| 10 = SLEEP | WDT enabled while running and disabled in Sleep. SWDTEN is ignored. |
| 01 = SWDTEN | WDT controlled by the SWDTEN bit in the WDTCN register |
| 00 = OFF | WDT disabled. SWDTEN is ignored. |

| bit 2 | Unimplemented: Read as ‘1’ |
| bit 1-0 | **FOSC<1:0>**: Oscillator Selection bits |
| 11 = ECH | External Clock, High-Power mode: CLKI on OSC1/CLKI |
| 10 = ECM | External Clock, Medium-Power mode: CLKI on OSC1/CLKI |
| 01 = ECL | External Clock, Low-Power mode: CLKI on OSC1/CLKI |
| 00 = INTOSC | I/O function on OSC1/CLKI |

Note 1: Enabling Brown-out Reset does not automatically enable Power-up Timer.
Note 2: Once enabled, code-protect can only be disabled by bulk erasing the device.

</tbody>
</table>

**Note 1:** This bit cannot be programmed to '0' when Programming mode is entered via LVP.

**Note 2:** The DEBUG bit in Configuration Words is managed automatically by device development tools including debuggers and programmers. For normal device operation, this bit should be maintained as a '1'.

**Note 3:** See Vbor parameter for specific trip point voltages.
4.0 PROGRAM/VERIFY MODE

In Program/Verify mode, the program memory and the configuration memory can be accessed and programmed in serial fashion. ICSPDAT and ICSPCLK are used for the data and the clock, respectively. All commands and data words are transmitted LSb first. Data changes on the rising edge of the ICSPCLK and is latched on the falling edge. In Program/Verify mode, both the ICSPDAT and ICSPCLK are Schmitt Trigger inputs. The sequence that enters the device into Program/Verify mode places all other logic into the Reset state. Upon entering Program/Verify mode, all I/Os are automatically configured as high-impedance inputs and the address is cleared.

4.1 High-Voltage Program/Verify Mode Entry and Exit

There are two different methods of entering Program/Verify mode via high voltage:

- VPP – First entry mode
- VDD – First entry mode

4.1.1 VPP – FIRST ENTRY MODE

To enter Program/Verify mode via the VPP-first method, the following sequence must be followed:

1. Hold ICSPCLK and ICSPDAT low. All other pins should be unpowered.
2. Raise the voltage on MCLR from 0V to VIHH.
3. Raise the voltage on VDD from 0V to the desired operating voltage.

The VPP-first entry prevents the device from executing code prior to entering Program/Verify mode. For example, when the Configuration Word has MCLR disabled (MCLRE = 0), the power-up time is disabled (PWRTE = 0), the internal oscillator is selected (FOSC = 100), and RA0 and RA1 are driven by the user application, the device will execute code. Since this may prevent entry, VPP-First Entry mode is strongly recommended. See the timing diagram in Figure 8-2.

4.1.2 VDD – FIRST ENTRY MODE

To enter Program/Verify mode via the VDD-first method, the following sequence must be followed:

1. Hold ICSPCLK and ICSPDAT low.
2. Raise the voltage on VDD from 0V to the desired operating voltage.
3. Raise the voltage on MCLR from VDD or below to VIHH.

The VDD-first method is useful when programming the device when VDD is already applied, for it is not necessary to disconnect VDD to enter Program/Verify mode. See the timing diagram in Figure 8-1.

4.1.3 PROGRAM/VERIFY MODE EXIT

To exit Program/Verify mode take MCLR to VDD or lower (VIL). See Figures 8-3 and 8-4.

4.2 Low-Voltage Programming (LVP) Mode

The Low-Voltage Programming mode allows the devices to be programmed using VDD only, without high voltage. When the LVP bit of the Configuration Word 2 register is set to ‘1’, the low-voltage ICSP programming entry is enabled. To disable the Low-Voltage ICSP mode, the LVP bit must be programmed to ‘0’. This can only be done while in the High-Voltage Entry mode.

Entry into the Low-Voltage ICSP Program/Verify mode requires the following steps:

1. MCLR is brought to VIL.
2. A 32-bit key sequence is presented on ICSPDAT, while clocking ICSPCLK.

The key sequence is a specific 32-bit pattern, '0100 1101 0100 0011 0100 1000 0101 0000' (more easily remembered as MCHP in ASCII). The device will enter Program/Verify mode only if the sequence is valid. The Least Significant bit of the Least Significant nibble must be shifted in first.

Once the key sequence is complete, MCLR must be held at VIL for as long as Program/Verify mode is to be maintained.

For low-voltage programming timing, see Figures 8-8 and 8-9.

Exiting Program/Verify mode is done by no longer driving MCLR to VIL. See Figures 8-8 and 8-9.

Note: To enter LVP mode, the LSb of the Least Significant nibble must be shifted in first. This differs from entering the key sequence on other parts.
4.3 Program/Verify Commands

These devices implement 13 programming commands, each six bits in length. The commands are summarized in Table 4-1.

Commands that have data associated with them are specified to have a minimum delay of \( T_{DLY} \) between the command and the data. After this delay, 16 clocks are required to either clock in or clock out the 14-bit data word. The first clock is for the Start bit and the last clock is for the Stop bit.

</tbody>
</table>
4.3.1 LOAD CONFIGURATION

The Load Configuration command is used to access the configuration memory (User ID Locations, Configuration Words, Calibration Words). The Load Configuration command sets the address to 8000h and loads the data latches with one word of data (see Figure 4-1).

After issuing the Load Configuration command, use the Increment Address command until the proper address to be programmed is reached. The address is then programmed by issuing either the Begin Internally Timed Programming or Begin Externally Timed Programming command.

Note: Externally timed writes are not supported for Configuration and Calibration bits. Any externally timed write to the Configuration or Calibration Word will have no effect on the targeted word.

The only way to get back to the program memory (address 0) is to exit Program/Verify mode or issue the Reset Address command after the configuration memory has been accessed by the Load Configuration command.

FIGURE 4-1: LOAD CONFIGURATION

![Diagram of Load Configuration](image1)

4.3.2 LOAD DATA FOR PROGRAM MEMORY

The Load Data for Program Memory command is used to load one 14-bit word into the data latches. The word programs into program memory after the Begin Internally Timed Programming or Begin Externally Timed Programming command is issued (see Figure 4-2).

FIGURE 4-2: LOAD DATA FOR PROGRAM MEMORY

![Diagram of Load Data for Program Memory](image2)
4.3.3 READ DATA FROM PROGRAM MEMORY

The Read Data from Program Memory command will transmit data bits out of the program memory map currently accessed, starting with the second rising edge of the clock input. The ICSPDAT pin will go into Output mode on the first falling clock edge, and it will revert to Input mode (high-impedance) after the 16th falling edge of the clock. If the program memory is code-protected (CP), the data will be read as zeros (see Figure 4-3).

**FIGURE 4-3: READ DATA FROM PROGRAM MEMORY**

4.3.4 INCREMENT ADDRESS

The address is incremented when this command is received. It is not possible to decrement the address. To reset this counter, the user must use the Reset Address command or exit Program/Verify mode and re-enter it.

If the address is incremented from address 7FFFh, it will wrap-around to location 0000h. If the address is incremented from FFFFh, it will wrap-around to location 8000h (see Figure 4-4).

**FIGURE 4-4: INCREMENT ADDRESS**
4.3.5  RESET ADDRESS

The Reset Address command will reset the address to 0000h, regardless of the current value. The address is used in program memory or the configuration memory (see Figure 4-5).

</tbody>
</table>

4.3.6  BEGIN INTERNALLY TIMED PROGRAMMING

A Load Configuration or Load Data for Program Memory command must be given before every Begin Programming command. Programming of the addressed memory will begin after this command is received. An internal timing mechanism executes the write. The user must allow for the program cycle time, TPINT, in order for the programming to complete.

The End Externally Timed Programming command is not needed when the Begin Internally Timed Programming is used to start the programming.

The program memory address that is being programmed is not erased prior to being programmed (see Figure 4-6).

</tr>
</tbody>
</table>
4.3.7 BEGIN EXTERNALLY TIMED PROGRAMMING

A Load Configuration or Load Data for Program Memory command must be given before every Begin Programming command. Programming of the addressed memory will begin after this command is received. To complete the programming, the End Externally Timed Programming command must be sent in the specified time window defined by TPEXT (see Figure 4-7).

Externally timed writes are not supported for Configuration and Calibration bits. Any externally timed write to the Configuration or Calibration Word will have no effect on the targeted word.

FIGURE 4-7: BEGIN EXTERNALLY TIMED PROGRAMMING

4.3.8 END EXTERNALLY TIMED PROGRAMMING

This command is required after a Begin Externally Timed Programming command is given. This command must be sent within the time window specified by TPEXT after the Begin Externally Timed Programming command is sent.

After sending the End Externally Timed Programming command, an additional delay (TDIS) is required before sending the next command. This delay is longer than the delay ordinarily required between other commands (see Figure 4-8).

FIGURE 4-8: END EXTERNALLY TIMED PROGRAMMING
4.3.9 BULK ERASE PROGRAM MEMORY

The Bulk Erase Program Memory command performs two different functions dependent on the current state of the address.

Address 0000h-7FFFh:
- Program Memory is erased
- Configuration Words are erased

Address 8000h-8008h:
- Program Memory is erased
- Configuration Words are erased
- User ID Locations are erased

A Bulk Erase Program Memory command should not be issued when the address is greater than 8008h.

**Note:** The code protection Configuration bit (CP) has no effect on the Bulk Erase Program Memory command.

4.3.10 ROW ERASE PROGRAM MEMORY

The Row Erase Program Memory command will erase an individual row. Refer to Table 4-2 for row sizes of specific devices and the PC bits used to address them. If the program memory is code-protected, the Row Erase Program Memory command will be ignored. When the address is 8000h-8008h, the Row Erase Program Memory command will only erase the user ID locations, regardless of the setting of the CP Configuration bit.

After receiving the Row Erase Program Memory command, the erase will not complete until the time interval, TERAR, has expired (see Figure 4-10).

**FIGURE 4-10: ROW ERASE PROGRAM MEMORY**

5.0 PROGRAMMING ALGORITHMS

The devices use internal latches to temporarily store the 14-bit words used for programming. Refer to Table 4-2 for specific latch information. The data latches allow the user to write the program words with a single Begin Externally Timed Programming or Begin Internally Timed Programming command. The Load Program Data or the Load Configuration command is used to load a single data latch. The data latch will hold the data until the Begin Externally Timed Programming or Begin Internally Timed Programming command is given.

The lower bits of the address define the data latch addresses and are aligned with the LSbs of the address. The upper bits of the address define the Flash program memory row. The upper bits that define the row address are indicated in Table 4-2.

When the Begin Externally Timed Programming or Begin Internally Timed Programming commands are given, the data contained in the data latches will be programmed into the corresponding addresses of the row specified by the upper bits of the PC. Writes cannot cross a physical row boundary. For example, in a 16-word latch device, attempting to write from address 0002h-0011h will result in data being written to 0010h-001Fh.

If more than the maximum number of latches are written without a Begin Externally Timed Programming or Begin Internally Timed Programming command, the data in the data latches will be overwritten. The following figures show the recommended flowcharts for programming.
FIGURE 5-1: DEVICE PROGRAM/VERIFY FLOWCHART

Note 1: See Figure 5-2.
Note 2: See Figure 5-5.
FIGURE 5-2: PROGRAM MEMORY FLOWCHART

Note 1: This step is optional if the device has already been erased or has not been previously programmed.
Note 2: If the device is code-protected or must be completely erased, then Bulk Erase the device per Figure 5-6.
Note 3: See Figure 5-3 or Figure 5-4.

FIGURE 5-6: ERASE FLOWCHART

Note: This sequence does not erase the Calibration Words.
6.0 CODE PROTECTION

Code protection is controlled using the $CP$ bit in Configuration Word 1. When code protection is enabled, all program memory locations (0000h-7FFFh) read as ‘0’. Further programming is disabled for the program memory (0000h-7FFFh). Program memory can still be programmed and read during program execution.

The user ID locations and Configuration Words can be programmed and read out regardless of the code protection settings.

6.1 Program Memory

Code protection is enabled by programming the $CP$ bit in Configuration Word 1 register to ‘0’.

The only way to disable code protection is to use the Bulk Erase Program Memory command.

7.0 HEX FILE USAGE

In the hex file there are two bytes per program word stored in the Intel® INHX32 hex format. Data is stored LSB first, MSB second. Because there are two bytes per word, the addresses in the hex file are 2x the address in program memory. (Example: The Configuration Word 1 is stored at 8007h. In the hex file this will be referenced as 1000Eh-1000Fh).

7.1 Configuration Word

To allow portability of code, it is strongly recommended that the programmer is able to read the Configuration Words and user ID locations from the hex file. If the Configuration Words information was not present in the hex file, a simple warning message may be issued. Similarly, while saving a hex file, Configuration Words and user ID information should be included.

7.2 Device ID

If a device ID is present in the hex file at 1000Ch-1000Dh (8006h on the part), the programmer should verify the device ID against the value read from the part. On a mismatch condition, the programmer should generate a warning message.

7.3 Checksum Computation

The checksum is calculated by two different methods dependent on the setting of the $CP$ Configuration bit.

<table>
<thead>
<tr>
<th>Device</th>
<th>Config. Word 1 Mask</th>
<th>Config. Word 2 Mask</th>
</tr>
</thead>
<tbody>
<tr>
<td>PIC16F1574</td>

</tr>
<tr>
<td>PIC16LF1579</td>
<td>0EFBh</td>
<td>3F07h</td>
</tr>
</tbody>
</table>

7.3.1 PROGRAM CODE PROTECTION DISABLED

With the program code protection disabled, the checksum is computed by reading the contents of the program memory locations and adding up the program memory data starting at address 0000h, up to the maximum user addressable location. Any Carry bits exceeding 16 bits are ignored. Additionally, the relevant bits of the Configuration Words are added to the checksum. All unimplemented Configuration bits are masked to ‘0’.
7.3.2 PROGRAM CODE PROTECTION
ENABLED

When the MPLAB IDE check box for Configure->ID Memory...-> Use Unprotected Checksum is checked, then the 16-bit checksum of the equivalent unprotected device is computed and stored in the user ID. Each nibble of the unprotected checksum is stored in the Least Significant nibble of each of the four user ID locations. The Most Significant checksum nibble is stored in the user ID at location 8000h, the second Most Significant nibble is stored at location 8001h, and so forth for the remaining nibbles and ID locations. The protected checksums in Table 7-2 assume that the Use Unprotected Checksum box is checked.

The checksum of a code-protected device is computed in the following manner: the Least Significant nibble of each user ID is used to create a 16-bit value. The Least Significant nibble of user ID location 8000h is the Most Significant nibble of the 16-bit value. The Least Significant nibble of user ID location 8001h is the second Most Significant nibble, and so forth for the remaining user IDs and 16-bit value nibbles. The resulting 16-bit value is summed with the Configuration Words. All unimplemented Configuration bits are masked to ‘0’.

**Note**

1: Externally timed writes are not supported for Configuration and Calibration bits.

2: Bulk-erased devices default to brown-out enabled. VDDMIN is 2.85 volts when performing low-voltage programming on a bulk-erased device, to ensure that the device is not held in Brown-out Reset.

APPENDIX A: REVISION HISTORY

Revision A (09/2014)

Initial release of this document.
Note the following details of the code protection feature on Microchip devices:

- Microchip products meet the specification contained in their particular Microchip Data Sheet.
- Microchip believes that its family of products is one of the most secure families of its kind on the market today, when used in the intended manner and under normal conditions.
- There are dishonest and possibly illegal methods used to breach the code protection feature. All of these methods, to our knowledge, require using the Microchip products in a manner outside the operating specifications contained in Microchip’s Data Sheets. Most likely, the person doing so is engaged in theft of intellectual property.
- Microchip is willing to work with the customer who is concerned about the integrity of their code.
- Neither Microchip nor any other semiconductor manufacturer can guarantee the security of their code. Code protection does not mean that we are guaranteeing the product as “unbreakable.”

Code protection is constantly evolving. We at Microchip are committed to continuously improving the code protection features of our products. Attempts to break Microchip’s code protection feature may be a violation of the Digital Millennium Copyright Act. If such acts allow unauthorized access to your software or other copyrighted work, you may have a right to sue for relief under that Act.

Information contained in this publication regarding device applications and the like is provided only for your convenience and may be superseded by updates. It is your responsibility to ensure that your application meets with your specifications.

MICROCHIP MAKES NO REPRESENTATIONS OR WARRANTIES OF ANY KIND WHETHER EXPRESS OR IMPLIED, WRITTEN OR ORAL, STATUTORY OR OTHERWISE, RELATED TO THE INFORMATION, INCLUDING BUT NOT LIMITED TO ITS CONDITION, QUALITY, PERFORMANCE, MERCHANTABILITY OR FITNESS FOR PURPOSE. Microchip disclaims all liability arising from this information and its use. Use of Microchip devices in life support and/or safety applications is entirely at the buyer’s risk, and the buyer agrees to defend, indemnify and hold harmless Microchip from any and all damages, claims, suits, or expenses resulting from such use. No licenses are conveyed, implicitly or otherwise, under any Microchip intellectual property rights.

Microchip received ISO/TS-16949:2009 certification for its worldwide headquarters, design and wafer fabrication facilities in Chandler and Tempe, Arizona; Gresham, Oregon and design centers in California and India. The Company’s quality system processes and procedures are for its PIC® MCUs and dsPIC® DSCs, Keeloo® code hopping devices, Serial EEPROMs, microperipherals, nonvolatile memory and analog products. In addition, Microchip’s quality system for the design and manufacture of development systems is ISO 9001:2000 certified.
