1.0 INTRODUCTION

The Peripheral Trigger Generator (PTG) module is a user-programmable sequencer, which is capable of generating complex trigger signal sequences to coordinate the operation of other peripherals.

The PTG module is designed to interface with other modules, such as Analog-to-Digital Converter (ADC), output compare and PWM modules, timers and interrupt controllers.

1.1 Features

- Behavior is Step Command-Driven:
  - Step commands are 8 bits wide
- Commands are Stored in a Step Queue:
  - Queue depth is up to 32 entries
  - Programmable Step execution time (Step delay)
- Supports the Command Sequence Loop:
  - Can be nested one-level deep
  - Conditional or unconditional loop
  - Two 16-bit loop counters
- 16 Hardware Input Triggers:
  - Sensitive to either positive or negative edges, or a high or low level
- One Software Input Trigger
- Generates up to 32 Unique Output Trigger Signals
- Generates Two Types of Trigger Outputs:
  - Individual
  - Broadcast
- Strobed Output Port for Literal Data Values:
  - 5-bit literal write (literal part of a command)
  - 16-bit literal write (literal held in the PTGL0 register)
- Generates up to 10 Unique Interrupt Signals
- Two 16-Bit General Purpose Timers
- Flexible Self-Contained Watchdog Timer (WDT) to Set an Upper Limit to Trigger Wait Time
- Single Step Command Capability in Debug mode
- Selectable Clock (System, Pulse-Width Modulator (PWM) or ADC)
- Programmable Clock Divider
Peripheral Trigger Generator (PTG)

Figure 1-1: PTG Block Diagram

Note 1: This is a dedicated Watchdog Timer for the PTG module and is independent of the device Watchdog Timer.
Note 2: Some devices support only PTGBTE<15:0> (16 outputs). Refer to the specific device data sheet for availability.

**Legend:**

- **HC** = Hardware Clearable bit
- **U** = Unimplemented bit, read as '0'
- **R** = Readable bit
- **W** = Writable bit
- **HS** = Hardware Settable bit
- **r** = Reserved bit
- **-n** = Value at POR
- '1' = Bit is set
- '0' = Bit is cleared
- **x** = Bit is unknown

**Note 1:** These bits apply to the **PTGWHI** and **PTGWLO** commands only.

**Note 2:** This bit is only used with the **PTGCTRL** Step command software trigger option.

**Note 3:** The **PTGSSEN** bit may only be written when in Debug mode.

**Note 4:** This bit is not available on all devices. Check the specific device data sheet for availability.
Register 2-1:   PTGCST: PTG Control/Status Low Register (Continued)

bit 1-0   PTGITM<1:0>: PTG Input Trigger Operation Selection
	11 = Single level detect with Step delay not executed on exit of command, regardless of the PTGCTRL command (Mode 3)
	10 = Single level detect with Step delay executed on exit of command (Mode 2)
	01 = Continuous edge detect with Step delay not executed on exit of command, regardless of the PTGCTRL command (Mode 1)
	00 = Continuous edge detect with Step delay executed on exit of command (Mode 0)

Note 1: These bits apply to the PTGWHI and PTGWLO commands only.

2: This bit is only used with the PTGCTRL Step command software trigger option.

3: The PTGSSEN bit may only be written when in Debug mode.

4: This bit is not available on all devices. Check the specific device data sheet for availability.

</tr>
</thead>
<tbody>
<tr>
<td>R/W-0</td>
<td>R/W-0</td>
</tr>
</tbody>
</table>

**Legend:**

- \(R\) = Readable bit
- \(W\) = Writable bit
- \(U\) = Unimplemented bit, read as '0'
- \(-n\) = Value at POR
- ‘1’ = Bit is set
- ‘0’ = Bit is cleared
- \(x\) = Bit is unknown

**Note 1:** These bits are read-only when the module is executing Step commands.
Register 2-7: PTGT1LIM: PTG Timer1 Limit Register

<table>
<thead>
<tr>
<th>bit 15</th>
<th>bit 8</th>
<th>bit 7</th>
<th>bit 0</th>
</tr>
</thead>
</table>

Legend:

R = Readable bit  W = Writable bit  U = Unimplemented bit, read as '0'
-n = Value at POR  '1' = Bit is set  '0' = Bit is cleared  x = Bit is unknown

bit 15-0  PTGT1LIM<15:0>: PTG Timer1 Limit Register bits

General purpose Timer1 Limit register.

Note 1: These bits are read-only when the module is executing Step commands.

Register 2-8: PTGSDLIM: PTG Step Delay Limit Register

<table>
<thead>
<tr>
<th>bit 15</th>
<th>bit 8</th>
<th>bit 7</th>
<th>bit 0</th>
</tr>
</thead>
</table>

Legend:

R = Readable bit  W = Writable bit  U = Unimplemented bit, read as '0'
-n = Value at POR  '1' = Bit is set  '0' = Bit is cleared  x = Bit is unknown

bit 15-0  PTGSDLIM<15:0>: PTG Step Delay Limit Register bits

This register holds a PTG Step delay value representing the number of additional PTG clocks between the start of a Step command and the completion of a Step command.

Note 1: These bits are read-only when the module is executing Step commands.
### Peripheral Trigger Generator (PTG)

#### Register 2-9: PTG0LIM: PTG Counter 0 Limit Register

<table>
<thead>
<tr>
<th>Bit</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>15-0</td>
<td>PTGC0LIM&lt;15:0&gt;</td>
<td>PTG Counter 0 Limit Register bits</td>
</tr>
</tbody>
</table>

This register is used to specify the loop count for the PTGJMPC0 Step command or as a Limit register for the General Purpose Counter 0.

**Note 1:** These bits are read-only when the module is executing Step commands.

#### Register 2-10: PTG1LIM: PTG Counter 1 Limit Register

<table>
<thead>
<tr>
<th>Bit</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>15-0</td>
<td>PTGC1LIM&lt;15:0&gt;</td>
<td>PTG Counter 1 Limit Register bits</td>
</tr>
</tbody>
</table>

This register is used to specify the loop count for the PTGJMPC1 Step command or as a Limit register for the General Purpose Counter 1.

**Note 1:** These bits are read-only when the module is executing Step commands.

bit 15-0  PTGL0<15:0>: PTG Literal 0 Register bits
This register holds a 16-bit value to be written to the AD1CHS0 register using the PTGCTRL command.

Note 1: These bits are read-only when the module is executing Step commands.

Note 2: The PTG strobe output is typically connected to the ADC Channel Select register. This allows the PTG to directly control ADC channel switching. See the specific device data sheet for connections of the PTG output.

bit 15-8

**STEP2n+1<7:0>**: PTG Command 4n+1 bits

A queue location for storage of the STEP2n+1 command byte, where ‘n’ is from PTGQUEn.

bit 7-0

**STEP2n<7:0>**: PTG Command 4n bits

A queue location for storage of the STEP2n command byte, where ‘n’ equals the odd numbered Step Queue Pointers.

**Note 1**: These bits are read-only when the module is executing Step commands.

\(^{2}\): Refer to Table 3-1 for the Step command encoding.
3.0 STEP COMMANDS AND FORMAT

The PTG operates using eleven 8-bit Step commands to perform higher level tasks. There are four types of Step commands:

• Input Event Control
• Control Functions
• Flow Control
• Output Generation

Combinations and sequences of these commands can be used to make decisions and take action without CPU intervention.

3.1 Input Event Control

There are two input event control commands, PTGWHI and PTGWLO, that wait for a high or low edge on one of the 16 PTGIx inputs. These commands are used in conjunction with a 4-bit OPTION field that specifies which PTGIx is used. Once the specified input transitions in the intended direction, the Step queue is incremented and the next Step command is evaluated. See Section 4.7.2 “Wait for Trigger Input” for additional information.

3.2 Control Functions

There are three commands for control functions, PTGCTRL, PTGADD and PTGCOPY. The PTGCTRL command controls the operation of the delay timers, software triggers and the strobe output. The PTGADD command is used to add the contents of the PTGHOLD register to other PTG registers, including the counters, timers, Step Delay and Literal register. The PTGCOPY command is used to copy the contents of the PTGHOLD register to other PTG registers, similar to the PTGADD command.

3.3 Flow Control

Flow control is accomplished using the 3 jump commands, PTGJMP, PTGJMPC0 and PTGJMPC1. These jump commands are 3 bits to allow a larger 5-bit OPTION to match that of the Queue Pointer, PTGQPTR. The PTGJMP command simply jumps to the specified queue location, whereas the PTGJMPCx commands are conditional jumps based on the comparison of the counters to the PTG Counter Limit registers (PTGCxLIM).

3.4 Output Generation

Output generation is achieved using the PTGTRIG, PTGIRQ and PTGSTRB commands. PTGTRIG is used to select and generate an output trigger (PTGOx). PTGTRIG also uses a 5-bit OPTION field to support the 32 PTGOS’ selections. The PTGIRQ command is used to generate an interrupt request with the OPTION field specifying the interrupt (PTGxIF). See Section 4.9 “PTG Module Outputs” for additional information on triggers and interrupts. The PTGSTRB command is used to generate a strobe output, which outputs 16 bits of data to another peripheral. See Section 4.10 “Strobe Output” for additional information.
Peripheral Trigger Generator (PTG)

Table 3-1 provides an overview of the PTG commands and Table 3-2 elaborates on the options available for each command. Example 3-1, Example 3-2 and Example 3-3 provide C code examples for command definitions and their options. Later examples in this FRM refer back to these examples.

    c1Limit = 0x1,
    t0Limit = 0x2,
    t1Limit = 0x3,
    stepDelay = 0x4,
    literal0 = 0x5,
} ADD_COPY_T;
```
Peripheral Trigger Generator (PTG)

4.0 MODULE OPERATION

4.1 PTG Description

The PTG module is a user-programmable sequencer for generating complex peripheral trigger sequences. The PTG module provides the ability to schedule complex peripheral operations, which would be difficult or impossible to achieve via a software solution.

The user writes 8-bit commands, called Step commands, to the PTG Queue registers (PTGQUE0-PTGQUE15). Each 8-bit Step command is made up of a command code and an option field. Table 3-1 shows the format and encoding of a Step command. Based on the commands, the PTG can interact with other peripherals, such as the PWM, ADC, MCCP, input capture and output compare. See the device-specific data sheet for availability of peripherals.

4.2 PTG Clock Selection

The PTG module has multiple clock options and has a selectable prescaler, which divides the PTG clock input from 1 to 32.

4.2.1 CLOCK SOURCE SELECTION

The PTGCLK<2:0> bits (PTGCON<15:13>) specify the clock source for the PTG clock generation logic. These clock sources are device-specific. Refer to the specific device data sheet for available sources.

4.2.2 CLOCK PRESCALER SELECTION

The PTGDIV<4:0> bits (PTGCON<12:8>) specify the prescaler value for the PTG clock generation logic. These bits can be written only when the PTG module is disabled (PTGEN = 0).

Note: Any attempt to write to the PTGDIV<4:0> bits or the PTGCLK<2:0> bits while PTGEN = 1 will have no effect.

4.2.3 MODULE ENABLE DELAY

Once the PTG module is enabled (PTGEN = 1), there is a delay before the PTG starts to execute commands. This delay is expressed in Equation 4-1. The PTG clock period is the effective clock after the prescaler.

Equation 4-1:

\[ \text{TDLYN} = 4 \times \text{PTG Clock Period (Maximum)} \]

The user must ensure that no control bits are modified during the delay. Also, no external triggers are asserted prior to the PTG state machine commencing execution; otherwise, the triggers will be missed.
4.3 Basic Operation

The user loads the Step commands (8-bit values) into the PTG Queue registers. The commands define a sequence of events for generating the trigger output signals to the peripherals. The Step commands can also be used to generate the interrupt requests to the processor.

The PTG module is enabled and clocked when the PTGEN bit (PTGCST<15>) = 1. While the PTGSTRT bit (PTGCST<7>) = 0, the PTG module is in the Halt state.

| Note 1: | The control registers cannot be modified when the PTG module is in the Halt state. |
| 2:      | The PTG module must be enabled (PTGEN = 1) prior to attempting to set the PTGSTRT bit. |
| 3:      | The user should not attempt to set the PTGEN and PTGSTRT bits within the same data write cycle. |

Subsequently, setting PTGSTRT = 1 will enable the module for Continuous mode execution of the Step command queue. The PTG sequencer will start to read the Step queue at the address held in the Queue Pointer (PTGQPTR). Each command byte is read, decoded and executed sequentially. The minimum duration of any Step command is one PTG clock as explained in Section 4.2 “PTG Clock Selection”.

Step commands will execute sequentially until any of the following occurs:

- A PTGJMP, PTGJMPC0 or PTGJMPC1 (flow change) Step command is executed.
- The user clears the PTGSTRT bit, stopping the PTG sequencer. No further Step commands are read/decoded and execution halts.
- The internal Watchdog Timer overflows, clearing the PTGSTRT bit and stopping the PTG sequencer. No further Step commands are read/decoded and execution halts.
- The PTG module is disabled (PTGEN = 0).

The Step commands can also be made to wait on a condition, such as an input trigger edge, a software trigger or a timer match, before continuing execution. For more information, refer to Section 4.11 “Stopping the Sequencer”.

Note 1: The control registers cannot be modified when the PTG module is in the Halt state.
2: The PTG module must be enabled (PTGEN = 1) prior to attempting to set the PTGSTRT bit.
3: The user should not attempt to set the PTGEN and PTGSTRT bits within the same data write cycle.
Peripheral Trigger Generator (PTG)

4.4 Control Register Access

When the PTG module is enabled (PTGEN = 1), writes are inhibited to all control registers with the exception of the PTGCST register, which may be read and written to as normal. When the PTG module is enabled (PTGEN = 1), reads can be performed from any control register at any time; however, the data read (control register or associated timer/counter value) will depend upon the state of the PTGIVIS bit (PTGCST<8>).

When the PTG module is disabled (PTGEN = 0), all control registers can be read and written to as normal. The PTGIVIS bit (PTGCST<8>) has no effect when PTGEN = 0, because all timers/counters will be cleared to zero; however, the values in the Limit register will stay same.

4.5 Step Queue Pointer

The PTG Step Queue Pointer register (PTGQPTR) holds the pointer to the PTG queue. The pointer is loaded from the PTGQPTR register when PTGEN = 1 and the PTGSTRT bit is set, and addresses the currently active Step command in the Step queue. The PTGQPTR register is cleared when the module is disabled (PTGEN = 0) or is in the Reset state. This is a one-time event that occurs on transition of the PTGEN bit from '1' to '0'.

The user can read the PTGQPTR register at any time. In the Disabled state (PTGEN = 0), a read returns the contents of the PTGQPTR register. In the Idle or Active state (PTGEN = 1), a read returns the contents of the pointer.

The PTGQPTR register is typically incremented during the first cycle of each command. The exceptions to this rule are:

- If the PTGJMP command is executed: The Step Queue Pointer is loaded with the target queue address
- If the PTGJMPCx command is executed and PTGCx is not zero: The Step Queue Pointer is loaded with the target queue address

4.6 Command Looping Control

Two 16-bit loop counters are provided (PTGC0 and PTGC1) that can be used by the PTGJMPCx command as a block loop counter or delay generator.

Each loop counter consists of an incrementing counter (PTGCx) and a Limit register (PTGCxLIM). The Limit register value can be changed by writing directly to the register (when the module is disabled) or by the PTG sequencer (when the module is enabled). The data read from the Limit register depends upon the state of the PTG Counter/Timer Visibility bit (PTGIVIS). The counters are cleared when the module is in the Reset state or when the PTG module is disabled (PTGEN = 0).
4.6.1 USING THE LOOP COUNTER AS A BLOCK LOOP COUNTER

The PTGJMPCx (Jump Conditional) command uses one of the loop counters to keep track of the number of times the PTGJMPCx command is executed, and can therefore, be used to create code block loops. This is useful in applications where a sequence of peripheral events needs to be repeated several times. The PTGJMPCx command allows the user to create code loops and use fewer Step commands.

Each time the PTGJMPCx command is executed, the corresponding internal loop counter is compared to its limit value. If the loop counter has not reached the limit value, the jump location is loaded into the PTGQPTR register and the loop counter is incremented by 1. The next command will be fetched from the new queue location. If the counter has reached the limit value, the sequencer proceeds to the next command (i.e., increments the Queue Pointer). While preparing for the next PTGJMPCx command loop execution, the corresponding loop counter is cleared (see Figure 4-1).

**Note:** The loop counter value can be modified (via the PTGADD or PTGCOPY command) prior to execution of the first iteration of the command loop.

The provision for two separate loop counters and associated PTGJMPCx commands allows for the nested loops to be supported (one-level deep). There are no restrictions with regard to which PTGJMPCx command resides in the inner or outer loops.

**Figure 4-1: Implementing Block Loop Diagram**

```
Execute PTGJMPC0

If PTGC0 ≥ PTGC0LIM

No

Continue Jump (Queue Pointer Jump Location)
PTGC0++

Yes

Do not Jump (Queue Pointer ++)
PTGC0 = 0
```
Peripheral Trigger Generator (PTG)

4.7 Sequencer Operation

All commands are executed in a single cycle, except for the flow change commands and the commands that are waiting for an external input.

4.7.1 STEP COMMAND DURATION

By default, each Step command executes in one PTG clock period. There are several methods to slow the execution of the Step commands:

- Wait for a trigger input
- Wait for a GP timer (PTGTxLIM)
- Insert a delay loop using the PTGJMP and PTGJMPCx commands
- Enable and insert a Step delay (PTGSDLIM) after execution of each command

4.7.2 WAIT FOR TRIGGER INPUT

The PTG module can support up to 16 independent trigger inputs. The PTG inputs, PTGI0 through PTGI15, are device-specific; refer to the device data sheet for availability. The user can specify a Step command that waits for a positive or negative edge, or a high or low level, of the selected input signal to occur. The operating mode is selected by the PTGITM<1:0> bits in the PTGCST register.

The PTGWHI command looks for a positive edge or high state to occur on the selected trigger input. The PTGWLO command looks for a negative edge or low state to occur on the selected trigger input. The PTG repeats the trigger input command (i.e., effectively waits) until the selected signal becomes valid before continuing the Step command execution.

The minimum execution time to wait for a trigger is one PTG clock. There is no limit for the PTG wait for a trigger input other than that enforced by the Watchdog Timer. Refer to Section 4.8 “PTG Watchdog Timer” for more information.

The PTG module supports four input trigger command operating modes (Mode 0-Mode 3), which are selected by the PTGITM<1:0> bits in the PTGCST register.

| Note: | If the Step delay is disabled, Mode 0 and Mode 1 are equivalent in operation, and Mode 2 and Mode 3 are equivalent in operation. |

4.7.2.1 Mode 0: PTGITM<1:0> = 0x00

(Continuous Edge Detect with Step Delay at Exit)

In this mode, the selected trigger input is continuously tested starting immediately after the PTGWHI or PTGWLO command is executed. When the trigger edge is detected, the command execution completes.

If the Step delay counter is enabled, the Step delay will be inserted (once) after the valid edge is detected and after the command execution.

If the Step delay counter is not enabled, the command will complete after the valid edge is detected and execution of the subsequent command will commence immediately.

| Note: | The edge detect logic is reset after the command execution is complete (i.e., prior to any Step delay associated with the command). For the edge to be detected, the edge should occur during the PTGWHI or PTGWLO command execution, or during the Step delay of the prior command. |
Figure 4-2 shows an example timing diagram of Mode 0 operation.

4.7.2.2 Mode 1: PTGTM<1:0> = 0x01
(Continuous Edge Detect without Step Delay at Exit)
In this mode, the selected trigger input is continuously tested starting immediately after the PTGWHI or PTGWLO command is executed. When the trigger edge is detected, the command execution completes.
Regardless of whether the Step delay counter is enabled or disabled, the Step delay will not be inserted after the command execution has completed.

Note: The edge detect logic is reset after the command execution completes. To be detected, the edge may therefore occur during the PTGWHI or PTGWLO command execution, or during the Step delay of the prior command.

Figure 4-3 shows an example timing diagram of Mode 1 operation.

Note: ‘EX’ indicates execution of the PTG Step command.
4.7.2.3 Mode 2: PTG_ITM<1:0> = 0x10  
(Sampled Level Detect with Step Delay at Exit)

In this mode, the selected trigger input is sample tested for a valid level immediately after the PTGWHI or PTGWLO command is executed; the trigger input is tested (once per PTG clock).

If the trigger does not occur, and the Step delay is enabled, the command waits for the Step delay to expire before testing the trigger input again. When the trigger occurs, the command execution completes and the Step delay is reinserted.

If the trigger does not occur and the Step delay is disabled, the command immediately tests the trigger input again during the next PTG clock cycle. When the trigger occurs, the command execution completes and execution of the subsequent command will commence immediately.

**Note 1:** As this operating mode is level-sensitive, if the input trigger level is true at the start of execution of the PTGWHI or PTGWLO command, the input test will be instantly satisfied.

2: The input is not latched, therefore, it must be valid when the command executes in order to be recognized.

Figure 4-4 shows an example timing diagram of Mode 2 operation.

**Figure 4-4: Operation of Level-Sensitive Command with Exit Step Delay**

Note: 'EX' indicates execution of the PTG Step command.
4.7.2.4 Mode 3: PTGITM<1:0> = 0x11
(Sampled Level Detect without Step Delay at Exit)

In this mode, the selected trigger input is sample tested for a valid level immediately after the PTGWHI or PTGWLO command is executed; the trigger input is tested (once per PTG clock).

If the trigger does not occur and the Step delay is enabled, the command waits for the Step delay to expire before testing the trigger input again. When the trigger is found to be true, the command execution completes and execution of the subsequent command will commence immediately. The Step delay is not inserted.

If the trigger does not occur and the Step delay is disabled, the command immediately tests the trigger input again during the next PTG clock cycle. When the trigger occurs, the command execution completes and execution of the subsequent command will commence immediately.

**Note 1:** As this operating mode is level-sensitive, if the input trigger level is true at the start of execution of the PTGWHI or PTGWLO command, the input test will be instantly satisfied.

**2:** The input is not latched, therefore, it must be valid when the command executes in order to be recognized.

Figure 4-5 shows an example timing diagram of Mode 3 operation.
4.7.3 WAIT FOR SOFTWARE TRIGGER

The user can set either a PTGCTRL 0x1011 (edge-triggered) or PTGCTRL 0x1010 (level-triggered) command to wait for a software generated trigger. This trigger is generated by setting the PTGSWT bit (PTGCST<10>).

The PTGCTRL 0x1011 command is sensitive only to the PTGSWT bit transition from '0' to '1'. This transition must occur during the command execution; otherwise, the command will continue to wait. The PTGSWT bit is automatically cleared by hardware on completion of the PTGCTRL 0x1011 command execution, initializing the bit for the next software trigger command. Figure 4-6 explains the operation of the wait for edge-based software trigger.

Figure 4-6: Operation of Wait for Edge-Based Software Trigger

The PTGCTRL 0x1010 command is sensitive to the level of the PTGSWT bit. This command waits until PTGSWT = 1. It will complete immediately if PTGSWT = 1 upon entry to the command. The PTGSWT bit is not automatically cleared by the PTGCTRL 0x1010 command. If desired, the PTGSWT bit can be cleared by the user application on completion of the PTGCTRL 0x1010 command execution. Figure 4-7 explains the operation of the wait for the level-based software trigger.

Figure 4-7: Operation of Wait for Level-Based Software Trigger

The PTGSWT bit, along with a PTG Step command, generates an interrupt that allows the user to coordinate activity between the PTG module and the application software.

Note: The level-sensitive software trigger (PTGCTRL 0x1010) is not available on all devices. For details, refer to the specific device data sheet.
4.7.4 WAIT FOR GP TIMER

The PTG has two internal dedicated 16-bit General Purpose (GP) timers (PTGT0 and PTGT1), which can be used by the sequencer to wait for a specified period. The Step commands are available for loading, modifying or initializing the GP timers.

Each GP timer consists of an incrementing timer (PTGTx) and a Limit register (PTGTxLIM). The Limit register value can be changed by a CPU write (when the module is disabled) or by the PTG sequencer (when the module is enabled). Data read from the Limit register depends upon the state of the PTG Counter/Timer Visibility bit (PTGIVIS).

When running, the timers increment on the rising edge of the PTG clock, which is defined in the PTGCST register. The user can specify a wait operation using a GP timer by executing the appropriate PTGCTRL 0x1000 or PTGCTRL 0x1001 command (wait for selected GP timer).

When waiting for the GP timer, the command will wait until the value of the timer (Timer0 or Timer1) reaches its respective limit value (PTGT0LIM or PTGT1LIM). On reaching the limit value, the Step command execution completes and the next command will start. The timer is also cleared for its next use. All timers are cleared when the device is in the Reset state or when the PTG module is disabled (PTGEN = 0).

4.7.5 STEP COMMAND DELAY

The Step Delay Timer (SDLY) is a convenient method to make each Step command consume a specific amount of time. Normally, the user specifies a Step delay equal to the duration of a peripheral function, such as the ADC conversion time. The Step delay enables the user to generate the trigger output signals at a controlled rate, thereby avoiding overload on the target peripheral.

The PTGSDLIM register defines the additional time duration of each Step command in terms of PTG clocks.

By default, the SDLY is disabled. The user can enable and disable the SDLY via the PTGCTRL 0x0110 or PTGCTRL 0x0010 command, which can be placed in the Step queue.

When operating, the SDLY increments at the PTG clock rate defined in the PTGCST register. The PTGSDLIM register value is referred to as the Step delay timer limit value. The Step delay is inserted after each command is executed, so that all Step commands are stalled until the PTGSD timer reaches its limit value. On reaching the limit value, the command execution completes and the next command starts execution. The timer is also cleared during execution of each command, so that it is ready for the next command execution.

Note: The PTGSDLIM register value of '0x0000' does not insert the additional PTG clocks when the Step delay timer is enabled. The PTGSDLIM register value of '0x0001' inserts a single PTG Step delay (1 PTG clock) into every subsequent instruction after the Step delay timer is enabled.

The trigger sources for the edge-sensitive commands (PTGCTRL 0x1011 and PTGWHI/PTGWLO when operated in Edge-Sensitive mode) have an additional hardware, external to the sequencer, to recognize the appropriate edge transition. The hardware is reset at the end of each command to maintain the edge-sensitive nature of these input triggers. If an additional valid edge occurs during a Step delay that has been inserted after the Step command has executed, it will not be recognized by any subsequent Step command. Figure 4-8 explains the operation of the Step command delay.

Figure 4-8: Operation of Step Command Delay

Note: ‘EX’ indicates execution of the PTG Step command.
4.8 PTG Watchdog Timer

A Watchdog Timer (WDT) is required as the PTG can wait indefinitely for an external event when executing the following commands:

- Wait for hardware trigger positive edge or high state (PTGWHI)
- Wait for hardware trigger negative edge or low state (PTGWLO)

The WDT is enabled and it starts counting when the command starts to execute. It is disabled when the command completes execution and prior to any Step delay insertion. All other commands execute with the predefined cycle counts.

*Note:* The PTG Watchdog Timer is not required during execution of the PTGCTRL 0x1011 or PTGCTRL 0x1010 command. It is assumed that correct operation of the device will be monitored through other means.

4.8.1 OPERATION OVERVIEW

If an expected event fails to arrive before the WDT time-out period expires, the PTG module:

1. Aborts the (failing) command underway.
2. Halts the sequencer (PTGSTRT = 0).
4. Issues a Watchdog Timer error interrupt to the processor.

The user can either use the Watchdog Timer error interrupt or periodically poll the PTGWDTO bit (PTGCST<6>) to determine that a WDT event has occurred.

4.8.2 CONFIGURATION

The WDT is configured by setting the PTGWDT<2:0> bits (PTGCON<2:0>). The WDT counts the PTG clocks as defined by the PTGCLK<2:0> and PTGDIV<4:0> bits in the PTGCON register. For more information, refer to Section 4.2 “PTG Clock Selection”. The WDT time-out count value is selected by using the PTGWDT<2:0> bits and is disabled when PTGWDT<2:0> = 0x000.

*Note 1:* The WDT is disabled prior to insertion of any Step delay; therefore, the user does not need to account for the Step delay when calculating a suitable WDT time-out value.

2: Some bits within the PTGCON register are read-only when PTGSTRT = 1 (Sequencer executing commands). Refer to Register 2-2.

4.8.3 WATCHDOG TIMER EVENT RECOVERY

If a WDT event occurs, the user has the option to take the necessary action to identify and fix the problem, and then continue the Step command sequence, or can simply restart the sequence.

To clear the PTGWDTO bit and to restart the PTG Sequencer from the start of the Step queue, disable (PTGEN = 0) and re-enable (PTGEN = 1) the PTG module, and then restart execution (PTGSTRT = 1).

Alternatively, as the Sequencer is only halted (not reset), the user has the option to examine the PTGQPTR register to identify which Step command was the source of the problem and can then take a corrective action. The offending command is aborted prior to the PTGQPTR update. Therefore, it will still address the failing command after the WDT event. After the PTGWDTO bit is cleared, the Step queue can be restarted at the same command by setting PTGSTRT = 1.

*Note:* The user should clear the PTGWDTO bit after a WDT event. Failing to clear the bit will not interfere with the subsequent module operation, but it will not be possible for the bit to poll any future WDT events.
4.9 PTG Module Outputs

The PTG module can generate trigger, interrupt and strobed data outputs by execution of specific Step commands.

4.9.1 TRIGGER OUTPUTS

The PTG module can generate up to 32 unique trigger output signals. There are two types of trigger output functions:

- Individual
- Broadcast

The PTG module can generate an individual output trigger on any one of the trigger outputs using the PTGTRIG command. The trigger outputs are device-specific. Refer to the specific device data sheet for availability.

The individual trigger outputs are typically used to trigger individual ADC input conversion operations, but can be assigned to any function, including general purpose I/O ports. When the PTG module is used with a compatible peripheral, such as the ADC module, the individual trigger output signals of the PTG are individually assigned to specific analog input conversion controllers within the ADC module.

The broadcast trigger output feature is specified by the PTGBTE/PTGBTEH registers. Each bit in the PTGBTE/PTGBTEH registers corresponds to an associated individual trigger output. If a bit is set in the PTGBTE/PTGBTEH registers, and a broadcast trigger Step command (PTGCTRL 0x1111) is executed, the corresponding individual trigger output is asserted. The broadcast trigger output enables the user to simultaneously generate a large number of trigger outputs with a single Step command.

4.9.2 INTERRUPT OUTPUTS

The PTG module can generate up to 16 unique interrupt request signals. These signals are useful for interacting with an application software to create more complex functions.

The PTG module can generate an individual interrupt pulse by using the PTGIRQ command.

4.10 Strobe Output

The strobe output of the PTG module can be used to output data from the PTG module. Typically, this output is connected to the ADC Channel Selection register, allowing the PTG to loop through ADC channels. The device-specific data sheet will indicate how the PTG strobe output is connected to other peripherals.

The PTGCTRL 0x1110 command writes the PTGL0 register contents to the strobe output. The PTGL0 register can be modified by using the PTGADD and PTGCOPY commands.

The PTGCTRL 0x1100 command writes the PTGC0 register contents to the strobe output. The PTGCTRL 0x1101 command writes the PTGC1 register contents to the strobe output.
4.10.1 OUTPUT TIMING

All triggers, interrupts and data strobe outputs are internally asserted by the PTG state machine when the corresponding Step command execution starts (i.e., before any additional time specified by the Step delay timer) on the rising edge of the PTG execution clock.

**Note:** If a command has triggered the pulse-width delay counter, the counter is synchronously reset with respect to the PTG clock, terminating the pulse (subject to a minimum pulse width of 1 PTG clock cycle).

In Pulse mode (PTGTOGL = 0), the width of the trigger output signals is determined by the PTGPWD<3:0> bits (PTGCON<7:4>), and can be any value between 1 and 16 PTG clock cycles. The default value is 1 PTG clock cycle.

Refer to **Section 4.10.1.2 “TRIG Negation When PTGTOGL = 1”** when operating in Toggle mode (PTGTOGL = 1).

When globally controlled by the PTGCTRL 0x1111 broadcast trigger command, the TRIG output pulse width is determined by the PTGPWD<3:0> bits (PTGCON<7:4>), and can be any value between 1 and 16 PTG clock cycles. The default value is 1 PTG clock cycle.

**Note:** The trigger generated by using the PTGCTRL 0x1111 broadcast trigger command can only operate in Pulse mode (i.e., PTGTOGL = ‘don’t care’).

4.10.1.1 TRIG Negation When PTGTOGL = 0

If generating an individual trigger output, and when the PTGTOGL bit (PTGCST<12>) = 0, or if generating a broadcast trigger output, the TRIG output(s) pulse width is determined by the PTGPWD<3:0> bits.

4.10.1.2 TRIG Negation When PTGTOGL = 1

If generating an individual trigger output and when the PTGTOGL bit (PTGCST<12>) = 1, the TRIG outputs will remain set until the PTGTRIG command is executed again. On start of the PTGTRIG command execution, the TRIG outputs are toggled at the beginning of the PTG execution clock.

**Note:** The PTGTOGL bit has no effect on the operation of the PTGCTRL 0x1111 multiple trigger (broadcast) generation command. The exception cases are as follows:

- The pulse width of all broadcast triggers is always determined by the PTGPWD<3:0> bits.
- If a target trigger output is already in the logic ‘1’ state (because PTGTOGL is active), the PTGCTRL 0x1111 command will have no effect and the trigger output will remain at logic ‘1’.

4.11 Stopping the Sequencer

When the PTG module is disabled (PTGEN = 0), the PTG clocks are disabled (except the trigger pulse counter), the Sequencer stops execution and the module enters its lowest power state. The PTGSTRT, PTGSWT, PTGWDTO and PTGQPTR<4:0> bits are all reset. All other bits and registers are not modified. All of the control registers can be read or written when PTGEN = 0.

When the PTGEN bit is cleared, a command that is underway is immediately aborted if the command is waiting for any of the following actions:

- An input from another source
- A timer match
- The Step delay to expire (for more information, refer to **Section 4.7.5 “Step Command Delay”**)

All other commands are allowed to complete before the PTG module is disabled.

When the PTG module is halted, all of the control registers remain in their present state. The PTG module can be halted by the user by clearing the PTGSTRT bit, or in the event of a Watchdog Timer time-out, which also clears the PTGSTRT bit. Refer to **Section 4.8 “PTG Watchdog Timer”** for more information.
5.0 APPLICATION EXAMPLES

5.1 Generating Phase-Shifted Waveforms

Figure 5-1 shows an application example where the user needs to generate phase-shifted waveforms. In this example, Output Compare 1 uses Timer2 as the synchronization source to generate a pulse. The rising edge of the pulse is the trigger input to the PTG module. When the trigger is sensed, the PTG module triggers Output Compare 2, which uses the PTG module as the synchronization source to generate a phase-shifted waveform.

**Note:** This application example is only applicable to devices that have output compare and Timer2 peripherals. Refer to the device-specific data sheet for availability.

---

**Figure 5-1:** Phase-Shifted Waveform Example Application
Peripheral Trigger Generator (PTG)

Example 5-1 shows code for generating a phase-shifted waveform.

Example 5-1:  Generating Phase-Shifted Waveforms

```c

   // Initialize Output Compare Module
   OC2CON1 = 0x0; // Clear all control bits
   OC2CON2 = 0x0; // Clear all control bits
   OC2CON1bits.OCTSEL = 0x7; // Select peripheral clock as clock source
   OC2CON2bits.SYNCSEL = 0xA; // Select PTG as sync source
   OC2CON1bits.OCM = 0x5; // Double compare continuous pulse mode
}
```
5.2 Interleaving Samples Over Multiple Cycles

Figure 5-2 shows the waveforms of an application where the user needs to accurately measure the power in a system where the current load is highly dependent on temperature, voltage and user application. The current waveforms vary widely per user usage, but over a few PWM cycles, the waveforms are relatively stable.

The aim of this example is to collect many current and/or voltage readings over several PWM cycles in an interleaved manner. The data is stored in the memory during acquisition and is later processed (integrated) to yield an accurate power value.

This example shows a situation where it would not be practical or possible for software to accurately schedule the ADC samples.

![Figure 5-2: Example Application – Average Power Calculation](image)

**Note:** The trigger delay value is modified to make the subsequent sample triggers be shifted in time, thereby enabling the interleaving of the samples.
5.3 Interleaved Sampling Step Command Program

This section describes the Step command programming for implementing the timing sequence shown in Figure 5-2.

The following assumptions are made:

1. Trigger Input 1 is connected to the PWM signal. The rising edge of the PWM signal starts the sequence.
2. Output Trigger 3 is connected to the ADC module. This signal gives command to the ADC module to begin a sample and conversion process.
3. Interrupt 1 is used to indicate to the processor that a subsequence has started (provides status).
4. Interrupt 4 is used to indicate to the processor that the entire sequence has completed.
5. The ADC clock is selected as the PTG clock source.
6. The ADC clock is 14 MHz.
7. The initial trigger delay is 5 µs.
8. The second trigger delay is 6 µs.
9. In each PWM cycle, the ADC will be triggered 25 times.
10. The basic sequence is executed twice.

Initialize the following control registers:

- PTGT0LIM = 0x0046 (5 µs x 14 clocks/µs)
- PTGT1LIM = 0x000B ([1 µs x 14 clocks/µs] – 3 Step Clocks)
- PTGC0LIM = 0x0018 (total of 25 inner loop iterations)
- PTGC1LIM = 0x0001 (total of two outer loop iterations)
- PTG0LIM = 0x0046 (5 µs x 14 clocks/µs)
- PTGADJ = 0x000E (1 µs x 14 clocks/µs)
- PTG0LIM = 0x0000 (no Step delay)
- PTGBTE = 0x0000 (no broadcast triggers)
- PTGQPTR = 0x0000 (start of Step queue)
- PTGCST = 0x8200 (after PTGQPTR is initialized)

Example 5-2: Step Commands in PTGQUEn

```c
void PTG_InterleavedSamplingQueue(void)
{
    // Outer loop
    _STEP0 = PTGWHI(0x1);  // Wait for positive edge trigger 1
    _STEP1 = PTGCTRL(t0Wait);  // Start PTGT0, wait for time out
    _STEP2 = PTGIQRQ(0x1);  // Generate IRQ 1
    // Inner loop
    _STEP3 = PTGTRIG(0x3);  // Generate output trigger 3
    _STEP4 = PTGCTRL(t1Wait);  // Start PTGT1, wait for time out
    _STEP5 = PTGMP0C0(0x3);  // Go to STEP3 if PTGC0 != PTGC0LIM, increment PTGC0
    // End inner loop
    _STEP6 = PTGADD(t0Limit);  // Add PTGADJ to PTGT0LIM
    _STEP7 = PTGMP0C1(0x0);  // Add PTGADJ to PTGT0LIM
    // End outer loop
    _STEP8 = PTGIRQ(0x4);  // Generate IRQ 4
    _STEP9 = PTGCOPY(0x8);  // Copy PTG0LIM to PTGT0LIM (restore original value)
    _STEP10 = PTGMP0C0(0x0);  // Jump to start of queue
}
```

See Example 3-1 for PTG command definitions. See Example 3-2 and Example 3-3 for PTGCTRL, PTGADD and PTGCOPY command options.
5.4 Sampling at Multiple Rates

Figure 5-3 shows an application example wherein the aim is to sample an ADC input at a fast rate (1x rate), a second analog input at a slower rate (1/2 rate) and Analog Inputs 4 through 7 at a 1/8 rate. The example is of a motor control application using a Silicon Controlled Rectifier (SCR) that triggers at a specified time after the AC line zero crossing.

While this example uses the simple binary sampling ratios, the PTG module can generate a very wide range of sample ratios to meet the requirements of an application.

Figure 5-3: Example Application – Ratioed Sampling

- Rectified AC Voltage (50 Hz)
- Zero-Crossing Detect
- Load Current
- Broadcast Triggers 4 through 7 to Sample Analog Inputs 4 through 7 at 1/8 Rate
- Trigger Delay Timer = 2 ms
- Delay = (10 ms – 2 ms)/8 = 1 ms
- TRIAC Enabled via Trigger 1 Output
- Trigger Output 3 for Voltage Sampling (1/2 Rate)
- Trigger Output 2 for Current Sampling (1x)
5.5 Ratioed Sampling Step Command Program

This section describes the Step command programming for implementing the timing sequence shown in Figure 5-3. The following assumptions are made:

• Trigger Input 0 is connected to the zero-crossing detect. The rising edge of the zero-crossing detect signal starts the sequence
• The trigger delay from Trigger Input 0 to the generation of Trigger Output 1 is 2 ms
• Trigger Output 1 enables the SCR in the application circuit
• Trigger Output 2 is connected to the ADC to trigger sampling of the current measurement at 1 ms intervals
• Trigger Output 3 is connected to the ADC to trigger sampling of the supply voltage measurement at 2 ms intervals
• Trigger Outputs 4, 5, 6 and 7 are connected to the ADC to sample other data values once per cycle
• The ADC clock is selected as the PTG clock source
• The ADC clock is 14 MHz

Initialize the following control registers:

• PTG0LIM = 0x6D60 (2 ms x 14 clocks/µs)
• PTG1LIM = 0x36B0 (1 ms x 14 clocks/µs)
• PTGC0LIM = 0x0018 (total of 25 inner loop iterations)
• PTGC1LIM = 0x0001 (total of two outer loop iterations)
• PTG0HOLD = 0x0000 (not used)
• PTG0ADJ = 0x0000 (not used)
• PTG0SDLIM = 0x0000 (no Step delay)
• PTG0BTE = 0x00F0 (enable Broadcast Triggers 4-7)
• PTG0QPTR = 0x0000 (start of Step queue)
• PTG0CST = 0x8200 (after PTG0QPTR is initialized)
Peripheral Trigger Generator (PTG)

6.0 POWER-SAVING MODES

The PTG module supports three power-saving modes:

- Disabled: The PTG module is not clocked in this mode
- Idle: The processor core and selected peripherals are shut down
- Sleep: The entire device is shut down

6.1 Disabled Mode

When PTGEN = 1, the module is considered in an active mode and is fully powered and functional. When PTGEN = 0, the module is turned off. The PTG clock portions of the circuit are disabled for maximum current savings. Only the control registers remain functional for reading and writing to allow the software to change the module’s operational mode. The module sequencer is reset.

6.2 Idle Mode

To continue full module operation while the PTG module is in Idle mode, the PTGSIDL bit must be cleared prior to entry into Idle mode. If PTGSIDL = 1, the module will behave the same way in Idle mode as it does in Sleep mode.

6.3 Sleep Mode

If the PTG module enters Sleep mode while the module is enabled (PTGEN = 1), the module will be suspended in its current state until clock execution resumes. This situation should be avoided as it might result in unexpected operation. It is recommended that all peripherals be shut down in an orderly manner prior to entering Sleep mode.
7.0 RELATED APPLICATION NOTES

This section lists application notes that are related to this section of the manual. These application notes may not be written specifically for the dsPIC33/PIC24 product families, but the concepts are pertinent and could be used with modification and possible limitations. The current application notes related to the Peripheral Trigger Generator (PTG) module include the following:

<table>
<thead>
<tr>
<th>Title</th>
<th>Application Note #</th>
</tr>
</thead>
<tbody>
<tr>
<td>No application notes at this point of time.</td>
<td>N/A</td>
</tr>
</tbody>
</table>

**Note:** Please visit the Microchip web site ([www.microchip.com](http://www.microchip.com)) for additional Application Notes and code examples for the dsPIC33/PIC24 families of devices.
Peripheral Trigger Generator (PTG)

8.0 REVISION HISTORY

Revision A (September 2011)
This is the initial released version of this document.

Revision B (August 2017)

• Sections:
  - Moved register map to the front of the document to replace the “Status and Control Registers” section.
  - Updated Section 1.0 “Introduction”, Section 3.0 “Step Commands and Format”, Section 4.0 “Module Operation”, Section 4.1 “PTG Description”, Section 4.2 “PTG Clock Selection”, Section 4.2.3 “Module Enable Delay”, Section 4.2.1 “Clock Source Selection”, Section 4.3 “Basic Operation”, Section 4.4 “Control Register Access”, Section 4.6 “Command Looping Control”, Section 4.7 “Sequencer Operation”, Section 4.7.4 “Wait for GP Timer”, Section 4.8 “PTG Watchdog Timer”, Section 4.10 “Strobe Output”, Section 4.10.1 “Output Timing”, Section 4.10.1.2 “TRG Negation When PTGTOGL = 1”, Section 4.11 “Stopping the Sequencer” and Section 5.1 “Generating Phase-Shifted Waveforms”.
  - Removed Section 4.8 “Step Commands”.

• Figures:
  - Updated Figure 1-1.
  - Added Figure 4-1.
  - Removed Figure 4-9: “GP Timer” and Figure 4-11: “Literal ’0’”.

• Examples:
  - Updated Example 5-2.
  - Removed Example 32-1: “Generating Phase-Shifted Waveforms”.

• Tables:
  - Updated Table 2-1, Table 3-1 and Table 3-2.

• Registers:
  - Updated Register 2-1, Register 2-2, Register 2-3, Register 2-4 and Register 2-14.

Minor grammatical corrections throughout the document.
Note the following details of the code protection feature on Microchip devices:

- Microchip products meet the specification contained in their particular Microchip Data Sheet.
- Microchip believes that its family of products is one of the most secure families of its kind on the market today, when used in the intended manner and under normal conditions.
- There are dishonest and possibly illegal methods used to breach the code protection feature. All of these methods, to our knowledge, require using the Microchip products in a manner outside the operating specifications contained in Microchip’s Data Sheets. Most likely, the person doing so is engaged in theft of intellectual property.
- Microchip is willing to work with the customer who is concerned about the integrity of their code.
- Neither Microchip nor any other semiconductor manufacturer can guarantee the security of their code. Code protection does not mean that we are guaranteeing the product as “unbreakable.”

Code protection is constantly evolving. We at Microchip are committed to continuously improving the code protection features of our products. Attempts to break Microchip’s code protection feature may be a violation of the Digital Millennium Copyright Act. If such acts allow unauthorized access to your software or other copyrighted work, you may have a right to sue for relief under that Act.

Information contained in this publication regarding device applications and the like is provided only for your convenience and may be superseded by updates. It is your responsibility to ensure that your application meets with your specifications. MICROCHIP MAKES NO REPRESENTATIONS OR WARRANTIES OF ANY KIND WHETHER EXPRESS OR IMPLIED, WRITTEN OR ORAL, STATUTORY OR OTHERWISE, RELATED TO THE INFORMATION, INCLUDING BUT NOT LIMITED TO ITS CONDITION, QUALITY, PERFORMANCE, MERCHANTABILITY OR FITNESS FOR PURPOSE. Microchip disclaims all liability arising from this information and its use. Use of Microchip devices in life support and/or safety applications is entirely at the buyer's risk, and the buyer agrees to defend, indemnify and hold harmless Microchip from any and all damages, claims, suits, or expenses resulting from such use. No licenses are conveyed, implicitly or otherwise, under any Microchip intellectual property rights unless otherwise stated.

Trademarks

The Microchip name and logo, the Microchip logo, AnyRate, AVR, AVR logo, AVR Freaks, BeaconThings, BitCloud, CryptoMemory, CryptoRF, dsPIC, FlashFlex, flexPWR, Helda, JukeBlox, KEELOQ logo, KEELOQ logo, Kleer, LANCheck, LINK MD, maXSylum, maXTouch, Medialan, megaAVR, MOST, MOST logo, MPLAB, OptoLyzer, PIC, picoPower, PICSTART, PIC32 logo, Prochip Designer, QTouch, RightTouch, SAM-BA, SpyNIC, SST, SST Logo, SuperFlash, tinyAVR, UNI/O, and XMEGA are registered trademarks of Microchip Technology Incorporated in the U.S.A. and other countries.

ClockWorks, The Embedded Control Solutions Company, EtherSynch, Hyper Speed Control, HyperLight Load, IntellIMOS, mTouch, Precision Edge, and Quiet-Wire are registered trademarks of Microchip Technology Incorporated in the U.S.A.

SQTP is a service mark of Microchip Technology Incorporated in the U.S.A.

Silicon Storage Technology is a registered trademark of Microchip Technology Inc. in other countries.

GestIC is a registered trademark of Microchip Technology Germany II GmbH & Co. KG, a subsidiary of Microchip Technology Inc., in other countries.

All other trademarks mentioned herein are property of their respective companies.
