dsPIC33EPXXXGS70X/80X FAMILY

16-Bit Digital Signal Controllers for Digital Power Applications with Interconnected High-Speed PWM, ADC, PGA and Comparators

Operating Conditions
- 3.0V to 3.6V, -40°C to +85°C, DC to 70 MIPS
- 3.0V to 3.6V, -40°C to +125°C, DC to 60 MIPS

Flash Architecture
- Dual Partition Flash Program Memory with Live Update:
  - Supports programming while operating
  - Supports partition soft swap

Core: 16-Bit dsPIC33E CPU
- Code-Efficient (C and Assembly) Architecture
- Two 40-Bit Wide Accumulators
- Single-Cycle (MAC/MPY) with Dual Data Fetch
- Single-Cycle Mixed-Sign MUL plus Hardware Divide
- 32-Bit Multiply Support
- Four Additional Working Register Sets (reduces context switching)

Clock Management
- ±0.9% Internal Oscillator
- Programmable PLLs and Oscillator Clock Sources
- Fail-Safe Clock Monitor (FSCM)
- Independent Watchdog Timer (WDT)
- Fast Wake-up and Start-up

Power Management
- Low-Power Management modes (Sleep, Idle, Doze)
- Integrated Power-on Reset and Brown-out Reset
- 0.5 mA/MHz Dynamic Current (typical)
- 20 μA IDQ Current (typical)

High-Speed PWM
- Eight PWM Generators (two outputs per generator)
- Individual Time Base and Duty Cycle for each PWM
- 1.04 ns PWM Resolution (frequency, duty cycle, dead time and phase)
- Supports Center-Aligned, Redundant, Complementary and True Independent Output modes
- Independent Fault and Current-Limit Inputs
- Output Override Control
- PWM Support for AC/DC, DC/DC, Inverters, PFC and Lighting

Advanced Analog Features
- High-Speed ADC module:
  - 12-bit with 4 dedicated SAR ADC cores and one shared SAR ADC core
  - Configurable resolution (up to 12-bit) for each ADC core
  - Up to 3.25 Msps conversion rate per channel at 12-bit resolution
  - 11 to 22 single-ended inputs
  - Dedicated result buffer for each analog channel
  - Flexible and independent ADC trigger sources
  - Two digital comparators
  - Two oversampling filters for increased resolution
- Four Rail-to-Rail Comparators with Hysteresis:
  - Dedicated 12-bit Digital-to-Analog Converter (DAC) for each analog comparator
  - Up to two DAC reference outputs
  - Up to two external reference inputs
  - Two Programmable Gain Amplifiers:
    - Single-ended or independent ground reference
    - Five selectable gains (4x, 8x, 16x, 32x and 64x)
  - 40 MHz gain bandwidth

Interconnected SMPS Peripherals
- Reduces CPU Interaction to Improve Performance
- Flexible PWM Trigger Options for ADC Conversions
- High-Speed Comparator Truncates PWM (15 ns typical):
  - Supports Cycle-by-Cycle Current mode control
  - Current Reset mode (variable frequency)

Timers/Output Compare/Input Capture
- Five 16-Bit and up to Two 32-Bit Timers/Counters
- Four Output Compare (OC) modules, Configurable as Timers/Counters
- Four Input Capture (IC) modules
Communication Interfaces

- Two UART modules (15 Mbps):
  - Supports LIN/J2602 protocols and IrDA®
- Three Variable Width SPI modules with Operating modes:
  - 3-wire SPI
  - 8x16 or 8x8 FIFO mode
  - I²S mode
- Two I²C modules (up to 1 Mbaud) with SMBus Support
- Up to Two CAN modules
- Four-Channel DMA

Input/Output

- Constant-Current Source (10 µA nominal)
- Sink/Source up to 12 mA/15 mA, respectively; Pin-Specific for Standard VOH/VOL
- 5V Tolerant Pins
- Selectable, Open-Drain Pull-ups and Pull-Downs
- External Interrupts on all I/O Pins
- Peripheral Pin Select (PPS) to allow Function Remap with Six Virtual I/Os

Qualification and Class B Support

- AEC-Q100 REVG (Grade 1, -40°C to +125°C)
- Class B Safety Library, IEC 60730
- The 6x6x0.55 mm UQFN Package is Designed and Optimized to ease IPC9592B 2nd Level Temperature Cycle Qualification

Debugger Development Support

- In-Circuit and In-Application Programming
- Five Program and Three Complex Data Breakpoints
- IEEE 1149.2 Compatible (JTAG) Boundary Scan
- Trace and Run-Time Watch

Digital Peripherals

- Four Configurable Logic Cells
- Peripheral Trigger Generator

</table>

Note 1: The external clock for Timer1, Timer2 and Timer3 is remappable.
Note 2: PWM4 through PWM8 are remappable on 28/44/48-pin devices; on 64-pin devices, only PWM7/PWM8 are remappable.
Note 3: External interrupts, INT0 and INT4, are not remappable.

TO OUR VALUED CUSTOMERS

It is our intention to provide our valued customers with the best documentation possible to ensure successful use of your Microchip products. To this end, we will continue to improve our publications to better suit your needs. Our publications will be refined and enhanced as new volumes and updates are introduced.

If you have any questions or comments regarding this publication, please contact the Marketing Communications Department via E-mail at docerrors@microchip.com. We welcome your feedback.

Most Current Data Sheet

To obtain the most up-to-date version of this data sheet, please register at our Worldwide Web site at:

http://www.microchip.com

You can determine the version of a data sheet by examining its literature number found on the bottom outside corner of any page. The last character of the literature number is the version number, (e.g., DS30000000A is version A of document DS30000000).

Errata

An errata sheet, describing minor operational differences from the data sheet and recommended workarounds, may exist for current devices. As device/documentation issues become known to us, we will publish an errata sheet. The errata will specify the revision of silicon and revision of document to which it applies.

To determine if an errata sheet exists for a particular device, please check with one of the following:

• Microchip’s Worldwide Web site; http://www.microchip.com
• Your local Microchip sales office (see last page)

When contacting a sales office, please specify which device, revision of silicon and data sheet (include literature number) you are using.

Customer Notification System

Register on our web site at www.microchip.com to receive the most current information on all of our products.
1.0 DEVICE OVERVIEW

Note 1: This data sheet summarizes the features of the dsPIC33EPXXXGS70X/80X family of devices. It is not intended to be a comprehensive resource. To complement the information in this data sheet, refer to the related section of the "dsPIC33/PIC24 Family Reference Manual", which is available from the Microchip web site (www.microchip.com).

2: Some registers and associated bits described in this section may not be available on all devices. Refer to Section 4.0 “Memory Organization” in this data sheet for device-specific register and bit information.

This document contains device-specific information for the dsPIC33EPXXXGS70X/80X Digital Signal Controller (DSC) devices.

dsPIC33EPXXXGS70X/80X devices contain extensive Digital Signal Processor (DSP) functionality with a high-performance, 16-bit MCU architecture.

Figure 1-1 shows a general block diagram of the core and peripheral modules. Table 1-1 lists the functions of the various pins shown in the pinout diagrams.

3: The SCK3 pin is fixed on dsPIC33EPXXXGS706/806 and dsPIC33EPXXXGS708/808 devices.  
4: PPS is available on dsPIC33EPXXXGS702 devices only.
2.0 GUIDELINES FOR GETTING STARTED WITH 16-BIT DIGITAL SIGNAL CONTROLLERS

Note 1: This data sheet summarizes the features of the dsPIC33EPXXXGS70X/80X family of devices. It is not intended to be a comprehensive reference source. To complement the information in this data sheet, refer to the related section of the “dsPIC33/PIC24 Family Reference Manual”, which is available from the Microchip web site (www.microchip.com).

2: Some registers and associated bits described in this section may not be available on all devices. Refer to Section 4.0 “Memory Organization” in this data sheet for device-specific register and bit information.

2.1 Basic Connection Requirements

Getting started with the dsPIC33EPXXXGS70X/80X family requires attention to a minimal set of device pin connections before proceeding with development. The following is a list of pin names which must always be connected:

- All VDD and VSS pins (see Section 2.2 “Decoupling Capacitors”)
- All AVDD and AVSS pins regardless if ADC module is not used (see Section 2.2 “Decoupling Capacitors”)
- VCAP (see Section 2.3 “CPU Logic Filter Capacitor Connection (VCAP)”)
- MCLR pin (see Section 2.4 “Master Clear (MCLR) Pin”)
- PGECx/PGEDx pins used for In-Circuit Serial Programming™ (ICSP™) and debugging purposes (see Section 2.5 “ICSP Pins”)
- OSC1 and OSC2 pins when external oscillator source is used (see Section 2.6 “External Oscillator Pins”)

2.2 Decoupling Capacitors

The use of decoupling capacitors on every pair of power supply pins, such as VDD, VSS, AVDD and AVSS is required.

Consider the following criteria when using decoupling capacitors:

- **Value and type of capacitor**: Recommendation of 0.1 µF (100 nF), 10-20V. This capacitor should be a low-ESR and have resonance frequency in the range of 20 MHz and higher. It is recommended to use ceramic capacitors.

- **Placement on the printed circuit board**: The decoupling capacitors should be placed as close to the pins as possible. It is recommended to place the capacitors on the same side of the board as the device. If space is constricted, the capacitor can be placed on another layer on the PCB using a via; however, ensure that the trace length from the pin to the capacitor is within one-quarter inch (6 mm) in length.

- **Handling high-frequency noise**: If the board is experiencing high-frequency noise, above tens of MHz, add a second ceramic-type capacitor in parallel to the above described decoupling capacitor. The value of the second capacitor can be in the range of 0.01 µF to 0.001 µF. Place this second capacitor next to the primary decoupling capacitor. In high-speed circuit designs, consider implementing a decade pair of capacitances as close to the power and ground pins as possible. For example, 0.1 µF in parallel with 0.001 µF.

- **Maximizing performance**: On the board layout from the power supply circuit, run the power and return traces to the decoupling capacitors first, and then to the device pins. This ensures that the decoupling capacitors are first in the power chain. Equally important is to keep the trace length between the capacitor and the power pins to a minimum, thereby reducing PCB track inductance.
On boards with power traces running longer than six
inches in length, it is suggested to use a tank capacitor
for integrated circuits, including DSCs, to supply a local
power source. The value of the tank capacitor should
be determined based on the trace resistance that con-
nects the power supply source to the device and the
maximum current drawn by the device in the applica-
tion. In other words, select the tank capacitor so that it
meets the acceptable voltage sag at the device. Typical
values range from 4.7 µF to 47 µF.

2.3 CPU Logic Filter Capacitor
Connection (VCAP)

A low-ESR (< 0.5Ω) capacitor is required on the VCAP
pin, which is used to stabilize the voltage regulator
output voltage. The VCAP pin must not be connected to
VDD and must have a capacitor greater than 4.7 µF
(10 µF is recommended), 16V connected to ground. The
type can be ceramic or tantalum. See Section 30.0
“Electrical Characteristics” for additional information.

The placement of this capacitor should be close to the
VCAP pin. It is recommended that the trace length not
exceeds one-quarter inch (6 mm). See Section 27.4
“On-Chip Voltage Regulator” for details.

2.4 Master Clear (MCLR) Pin

The MCLR pin provides two specific device functions:

• Device Reset
• Device Programming and Debugging.

During device programming and debugging, the
resistance and capacitance that can be added to the
pin must be considered. Device programmers and
debuggers drive the MCLR pin. Consequently,
specific voltage levels (VIH and VIL) and fast signal
transitions must not be adversely affected. Therefore,
specific values of R and C will need to be adjusted
based on the application and PCB requirements.

For example, as shown in Figure 2-2, it is recom-
mended that the capacitor, C, be isolated from the
MCLR pin during programming and debugging opera-
tions.

Place the components as shown in Figure 2-2, within
one-quarter inch (6 mm) from the MCLR pin.
2.5  ICSP Pins

The PGECx and PGEDx pins are used for ICSP and debugging purposes. It is recommended to keep the trace length between the ICSP connector and the ICSP pins on the device as short as possible. If the ICSP connector is expected to experience an ESD event, a series resistor is recommended, with the value in the range of a few tens of Ohms, not to exceed 100 Ohms. Pull-up resistors, series diodes and capacitors on the PGECx and PGEDx pins are not recommended as they will interfere with the programmer/debugger communications to the device. If such discrete components are an application requirement, they should be removed from the circuit during programming and debugging. Alternatively, refer to the AC/DC characteristics and timing requirements information in the respective device Flash programming specification for information on capacitive loading limits and pin Voltage Input High (Vih) and Voltage Input Low (Vil) requirements.

Ensure that the “Communication Channel Select” (i.e., PGECx/PGEDx pins) programmed into the device matches the physical connections for the ICSP to MPLAB® PICkit™ 3, MPLAB ICD 3, or MPLAB REAL ICE™.

For more information on MPLAB ICD 2, MPLAB ICD 3 and REAL ICE connection requirements, refer to the following documents that are available on the Microchip web site.

- “Using MPLAB® ICD 3 In-Circuit Debugger” (poster) (DS51765)
- “Development Tools Design Advisory” (DS51764)
- “MPLAB® REAL ICE™ In-Circuit Emulator User’s Guide” (DS51616)
- “Using MPLAB® REAL ICE™ In-Circuit Emulator” (poster) (DS51749)

2.6  External Oscillator Pins

Many DSCs have options for at least two oscillators: a high-frequency primary oscillator and a low-frequency secondary oscillator. For details, see Section 9.0 “Oscillator Configuration” for details.

The oscillator circuit should be placed on the same side of the board as the device. Also, place the oscillator circuit close to the respective oscillator pins, not exceeding one-half inch (12 mm) distance between them. The load capacitors should be placed next to the oscillator itself, on the same side of the board. Use a grounded copper pour around the oscillator circuit to isolate them from surrounding circuits. The grounded copper pour should be routed directly to the MCU ground. Do not run any signal traces or power traces inside the ground pour. Also, if using a two-sided board, avoid any traces on the other side of the board where the crystal is placed. A suggested layout is shown in Figure 2-3.

FIGURE 2-3: SUGGESTED PLACEMENT OF THE OSCILLATOR CIRCUIT
2.7 Oscillator Value Conditions on Device Start-up

If the PLL of the target device is enabled and configured for the device start-up oscillator, the maximum oscillator source frequency must be limited to $3 \text{ MHz} < \text{Fin} < 5.5 \text{ MHz}$ to comply with device PLL start-up conditions. This means that if the external oscillator frequency is outside this range, the application must start up in the FRC mode first. The default PLL settings, after a POR with an oscillator frequency outside this range, will violate the device operating speed.

Once the device powers up, the application firmware can initialize the PLL SFRs, CLKDIV and PLLFBD, to a suitable value, and then perform a clock switch to the Oscillator + PLL clock source. Note that clock switching must be enabled in the device Configuration Word.

2.8 Unused I/Os

Unused I/O pins should be configured as outputs and driven to a logic low state. Alternatively, connect a 1k to 10k resistor between VSS and unused pins, and drive the output to logic low.

2.9 Targeted Applications

- Power Factor Correction (PFC)
  - Interleaved PFC
  - Critical Conduction PFC
  - Bridgeless PFC
- DC/DC Converters
  - Buck, Boost, Forward, Flyback, Push-Pull
  - Half/Full-Bridge
  - Phase-Shift Full-Bridge
  - Resonant Converters
- DC/AC
  - Half/Full-Bridge Inverter
  - Resonant Inverter

Examples of typical application connections are shown in Figure 2-4 through Figure 2-6.

FIGURE 2-4: INTERLEAVED PFC

FIGURE 2-5: PHASE-SHIFTED FULL-BRIDGE CONVERTER

dsPIC33EPXXXGS70X/80X FAMILY
FIGURE 2-6: OFF-LINE UPS
The dsPIC33EPXXXGS70X/80X family CPU has a 16-bit (data) modified Harvard architecture with an enhanced instruction set, including significant support for Digital Signal Processing (DSP). The CPU has a 24-bit instruction word with a variable length opcode field. The Program Counter (PC) is 23 bits wide and addresses up to 4M x 24 bits of user program memory space.

An instruction prefetch mechanism helps maintain throughput and provides predictable execution. Most instructions execute in a single-cycle effective execution rate, with the exception of instructions that change the program flow, the double-word move (MOV.D) instruction, PSV accesses and the table instructions. Overhead-free program loop constructs are supported using the DO and REPEAT instructions, both of which are interruptible at any point.

### Registers

The dsPIC33EPXXXGS70X/80X devices have sixteen, 16-bit Working registers in the programmer’s model. Each of the Working registers can act as a Data, Address or Address Offset register. The 16th Working register (W15) operates as a Software Stack Pointer for interrupts and calls.

In addition, the dsPIC33EPXXXGS70X/80X devices include four Alternate Working register sets which consist of W0 through W14. The Alternate Working registers can be made persistent to help reduce the saving and restoring of register content during Interrupt Service Routines (ISRs). The Alternate Working registers can be assigned to a specific Interrupt Priority Level (IPL1 through IPL7) by configuring the CTXTx<2:0> bits in the FALTREG Configuration register. The Alternate Working registers can also be accessed manually by using the CTXTSWP instruction. The CCTXI<2:0> and MCTXI<2:0> bits in the CTXTSTAT register can be used to identify the current, and most recent, manually selected Working register sets.

### Instruction Set

The instruction set for dsPIC33EPXXXGS70X/80X devices has two classes of instructions: the MCU class of instructions and the DSP class of instructions. These two instruction classes are seamlessly integrated into the architecture and execute from a single execution unit. The instruction set includes many addressing modes and was designed for optimum C compiler efficiency.

### Data Space Addressing

The base Data Space can be addressed as up to 4K words or 8 Kbytes, and is split into two blocks, referred to as X and Y data memory. Each memory block has its own independent Address Generation Unit (AGU). The MCU class of instructions operates solely through the X memory AGU, which accesses the entire memory map as one linear Data Space. Certain DSP instructions operate through the X and Y AGUs to support dual operand reads, which splits the data address space into two parts. The X and Y Data Space boundary is device-specific.

The upper 32 Kbytes of the Data Space memory map can optionally be mapped into Program Space (PS) at any 16K program word boundary. The program-to-Data Space mapping feature, known as Program Space Visibility (PSV), lets any instruction access Program Space as if it were Data Space. Refer to “Data Memory” (DS70595) in the “dsPIC33/PIC24 Family Reference Manual” for more details on PSV and table accesses.

On dsPIC33EPXXXGS70X/80X devices, overhead-free circular buffers (Modulo Addressing) are supported in both X and Y address spaces. The Modulo Addressing removes the software boundary checking overhead for DSP algorithms. The X AGU Circular Addressing can be used with any of the MCU class of instructions. The X AGU also supports Bit-Reversed Addressing to greatly simplify input or output data re-ordering for radix-2 FFT algorithms.

### Addressing Modes

The CPU supports these addressing modes:

- Inherent (no operand)
- Relative
- Literal
- Memory Direct
- Register Direct
- Register Indirect

Each instruction is associated with a predefined addressing mode group, depending upon its functional requirements. As many as six addressing modes are supported for each instruction.

### 3.5 Programmer’s Model

The programmer’s model for the dsPIC33EPXXXGS70X/80X family is shown in Figure 3-2. All registers in the programmer’s model are memory-mapped and can be manipulated directly by instructions. Table 3-1 lists a description of each register.

In addition to the registers contained in the programmer’s model, the dsPIC33EPXXXGS70X/80X devices contain control registers for Modulo Addressing, Bit-Reversed Addressing and interrupts. These registers are described in subsequent sections of this document.

All registers associated with the programmer’s model are memory-mapped, as shown in Table 3-1.

Legend:
- **C** = Clearable bit
- **R** = Readable bit
- **W** = Writable bit
- **U** = Unimplemented bit, read as ‘0’
- ‘-n’ = Value at POR
- ‘1’ = Bit is set
- ‘0’ = Bit is cleared
- ‘x’ = Bit is unknown

- **bit 15**
  - **OA**: Accumulator A Overflow Status bit
    - 1 = Accumulator A has overflowed
    - 0 = Accumulator A has not overflowed

- **bit 14**
  - **OB**: Accumulator B Overflow Status bit
    - 1 = Accumulator B has overflowed
    - 0 = Accumulator B has not overflowed

- **bit 13**
  - **SA**: Accumulator A Saturation ‘Sticky’ Status bit
    - 1 = Accumulator A is saturated or has been saturated at some time
    - 0 = Accumulator A is not saturated

- **bit 12**
  - **SB**: Accumulator B Saturation ‘Sticky’ Status bit
    - 1 = Accumulator B is saturated or has been saturated at some time
    - 0 = Accumulator B is not saturated

- **bit 11**
  - **OAB**: OA || OB Combined Accumulator Overflow Status bit
    - 1 = Accumulator A or B has overflowed
    - 0 = Neither Accumulator A or B has overflowed

- **bit 10**
  - **SAB**: SA || SB Combined Accumulator ‘Sticky’ Status bit
    - 1 = Accumulator A or B is saturated or has been saturated at some time
    - 0 = Neither Accumulator A or B is saturated

- **bit 9**
  - **DA**: DO Loop Active bit
    - 1 = DO loop is in progress
    - 0 = DO loop is not in progress

- **bit 8**
  - **DC**: MCU ALU Half Carry/Borrow bit
    - 1 = A carry-out from the 4th low-order bit (for byte-sized data) or 8th low-order bit (for word-sized data) of the result occurred
    - 0 = No carry-out from the 4th low-order bit (for byte-sized data) or 8th low-order bit (for word-sized data) of the result occurred

**Note 1:**
The IPL<2:0> bits are concatenated with the IPL<3> bit (CORCON<3>) to form the CPU Interrupt Priority Level. The value in parentheses indicates the IPL, if IPL<3> = 1. User interrupts are disabled when IPL<3> = 1.

**Note 2:**
The IPL<2:0> Status bits are read-only when the NSTDIS bit (INTCON1<15>) = 1.

**Note 3:**
A data write to the SR register can modify the SA and SB bits by either a data write to SA and SB or by clearing the SAB bit. To avoid a possible SA or SB bit write race condition, the SA and SB bits should not be modified using bit operations.
REGISTER 3-1:  SR: CPU STATUS REGISTER (CONTINUED)

bit 7-5  IPL<2:0>: CPU Interrupt Priority Level Status bits\(^{(1,2)}\)

111 = CPU Interrupt Priority Level is 7 (15); user interrupts are disabled
110 = CPU Interrupt Priority Level is 6 (14)
101 = CPU Interrupt Priority Level is 5 (13)
100 = CPU Interrupt Priority Level is 4 (12)
011 = CPU Interrupt Priority Level is 3 (11)
010 = CPU Interrupt Priority Level is 2 (10)
001 = CPU Interrupt Priority Level is 1 (9)
000 = CPU Interrupt Priority Level is 0 (8)

bit 4  RA: REPEAT Loop Active bit
1 = REPEAT loop is in progress
0 = REPEAT loop is not in progress

bit 3  N: MCU ALU Negative bit
1 = Result was negative
0 = Result was non-negative (zero or positive)

bit 2  OV: MCU ALU Overflow bit
This bit is used for signed arithmetic (2’s complement). It indicates an overflow of the magnitude that causes the sign bit to change state.
1 = Overflow occurred for signed arithmetic (in this arithmetic operation)
0 = No overflow occurred

bit 1  Z: MCU ALU Zero bit
1 = An operation that affects the Z bit has set it at some time in the past
0 = The most recent operation that affects the Z bit has cleared it (i.e., a non-zero result)

bit 0  C: MCU ALU Carry/Borrow bit
1 = A carry-out from the Most Significant bit of the result occurred
0 = No carry-out from the Most Significant bit of the result occurred

Note 1:  The IPL<2:0> bits are concatenated with the IPL<3> bit (CORCON<3>) to form the CPU Interrupt Priority Level. The value in parentheses indicates the IPL, if IPL<3> = 1. User interrupts are disabled when IPL<3> = 1.

2:  The IPL<2:0> Status bits are read-only when the NSTDIS bit (INTCON1<15>) = 1.

3:  A data write to the SR register can modify the SA and SB bits by either a data write to SA and SB or by clearing the SAB bit. To avoid a possible SA or SB bit write race condition, the SA and SB bits should not be modified using bit operations.

  - 001 = 1 DO loop is active
  
  - 000 = 0 DO loops are active

- **SATA**: ACMA Saturation Enable bit
  
  - 1 = Accumulator A saturation is enabled
  
  - 0 = Accumulator A saturation is disabled

- **SATB**: ACCB Saturation Enable bit
  
  - 1 = Accumulator B saturation is enabled
  
  - 0 = Accumulator B saturation is disabled

- **SATDW**: Data Space Write from DSP Engine Saturation Enable bit
  
  - 1 = Data Space write saturation is enabled
  
  - 0 = Data Space write saturation is disabled

- **ACCSAT**: Accumulator Saturation Mode Select bit
  
  - 1 = 9.31 saturation (super saturation)
  
  - 0 = 1.31 saturation (normal saturation)

- **IPL3**: CPU Interrupt Priority Level Status bit
  
  - 1 = CPU Interrupt Priority Level is greater than 7
  
  - 0 = CPU Interrupt Priority Level is 7 or less

### Notes:

1. This bit is always read as '0'.
2. The IPL3 bit is concatenated with the IPL<2:0> bits (SR<7:5>) to form the CPU Interrupt Priority Level.
REGISTER 3-2:  CORCON: CORE CONTROL REGISTER (CONTINUED)

bit 2  
**SFA:** Stack Frame Active Status bit
1 = Stack frame is active; W14 and W15 address 0x0000 to 0xFFFF, regardless of DSRPAG
0 = Stack frame is not active; W14 and W15 address the base Data Space

bit 1  
**RND:** Rounding Mode Select bit
1 = Biased (conventional) rounding is enabled
0 = Unbiased (convergent) rounding is enabled

bit 0  
**IF:** Integer or Fractional Multiplier Mode Select bit
1 = Integer mode is enabled for DSP multiply
0 = Fractional mode is enabled for DSP multiply

**Note 1:** This bit is always read as ‘0’.
2: The IPL3 bit is concatenated with the IPL<2:0> bits (SR<7:5>) to form the CPU Interrupt Priority Level.

DS70005258B-page 29
### 3.8 Arithmetic Logic Unit (ALU)

The dsPIC33EPXXXGS70X/80X family ALU is 16 bits wide and is capable of addition, subtraction, bit shifts and logic operations. Unless otherwise mentioned, arithmetic operations are two’s complement in nature. Depending on the operation, the ALU can affect the values of the Carry (C), Zero (Z), Negative (N), Overflow (OV) and Digit Carry (DC) Status bits in the SR register. The C and DC Status bits operate as Borrow and Digit Borrow bits, respectively, for subtraction operations.

The ALU can perform 8-bit or 16-bit operations, depending on the mode of the instruction that is used. Data for the ALU operation can come from the W register array or data memory, depending on the addressing mode of the instruction. Likewise, output data from the ALU can be written to the W register array or a data memory location.

Refer to the “16-bit MCU and DSC Programmer’s Reference Manual” (DS70157) for information on the SR bits affected by each instruction.

The core CPU incorporates hardware support for both multiplication and division. This includes a dedicated hardware multiplier and support hardware for 16-bit divisor division.

#### 3.8.1 MULTIPLIER

Using the high-speed, 17-bit x 17-bit multiplier, the ALU supports unsigned, signed or mixed-sign operation in several MCU Multiplication modes:

- 16-bit x 16-bit signed
- 16-bit x 16-bit unsigned
- 16-bit signed x 5-bit (literal) unsigned
- 16-bit signed x 16-bit unsigned
- 16-bit unsigned x 5-bit (literal) unsigned
- 16-bit unsigned x 16-bit signed
- 8-bit unsigned x 8-bit unsigned

#### 3.8.2 DIVIDER

The divide block supports 32-bit/16-bit and 16-bit/16-bit signed and unsigned integer divide operations with the following data sizes:

- 32-bit signed/16-bit signed divide
- 32-bit unsigned/16-bit unsigned divide
- 16-bit signed/16-bit signed divide
- 16-bit unsigned/16-bit unsigned divide

The quotient for all divide instructions ends up in W0 and the remainder in W1. 16-bit signed and unsigned DIV instructions can specify any W register for both the 16-bit divisor (Wn) and any W register (aligned) pair (W(m + 1):Wm) for the 32-bit dividend. The divide algorithm takes one cycle per bit of divisor, so both 32-bit/16-bit and 16-bit/16-bit instructions take the same number of cycles to execute.

### 3.9 DSP Engine

The DSP engine consists of a high-speed 17-bit x 17-bit multiplier, a 40-bit barrel shifter and a 40-bit adder/subtractor (with two target accumulators, round and saturation logic).

The DSP engine can also perform inherent accumulator-to-accumulator operations that require no additional data. These instructions are, ADD, SUB and NEG.

The DSP engine has options selected through bits in the CPU Core Control register (CORCON), as listed below:

- Fractional or Integer DSP Multiply (IF)
- Signed, Unsigned or Mixed-Sign DSP Multiply (USx)
- Conventional or Convergent Rounding (RND)
- Automatic Saturation On/Off for ACCA (SATA)
- Automatic Saturation On/Off for ACCB (SATB)
- Automatic Saturation On/Off for Writes to Data Memory (SATDW)
- Accumulator Saturation mode Selection (ACCSAT)

4.0 MEMORY ORGANIZATION

Note: This data sheet summarizes the features of the dsPIC33EPXXXGS70X/80X family of devices. It is not intended to be a comprehensive reference source. To complement the information in this data sheet, refer to “dsPIC33E/PIC24E Program Memory” (DS70000613) in the “dsPIC33/PIC24 Family Reference Manual”, which is available from the Microchip web site (www.microchip.com).

The dsPIC33EPXXXGS70X/80X family architecture features separate program and data memory spaces, and buses. This architecture also allows the direct access of program memory from the Data Space (DS) during code execution.

4.1 Program Address Space

The program address memory space of the dsPIC33EPXXXGS70X/80X family devices is 4M instructions. The space is addressable by a 24-bit value derived either from the 23-bit PC during program execution, or from table operation or Data Space remapping, as described in Section 4.9 “Interfacing Program and Data Memory Spaces”.

User application access to the program memory space is restricted to the lower half of the address range (0x000000 to 0x7FFFFFF). The exception is the use of TBLRD operations, which use TBLPAG<7> to permit access to calibration data and Device ID sections of the configuration memory space.

The program memory maps for dsPIC33EPXXXGS70X/80X devices not operating in Dual Partition mode are shown in Figure 4-1 and Figure 4-2.

The dsPIC33EPXXXGS70X/80X devices can operate in a Dual Partition Flash Program Memory mode, where the user Program Flash Memory is arranged as two separate address spaces, one for each of the Flash partitions. The Active Partition always starts at address, 0x000000, and contains half of the available Flash memory (64k/128k, depends on device). The Inactive Partition always starts at address, 0x400000, and implements the remaining half of Flash memory. As shown in Figure 4-3 and Figure 4-4, the Active and Inactive Partitions are identical, and both contain unique copies of the Reset vector, Interrupt Vector Tables (IVT and AIVT if enabled) and the Flash Configuration Words.
4.2 Unique Device Identifier (UDID)

All dsPIC33EPXXXGS70X/80X family devices are individually encoded during final manufacturing with a Unique Device Identifier or UDID. This feature allows for manufacturing traceability of Microchip Technology devices in applications where this is a requirement. It may also be used by the application manufacturer for any number of things that may require unique identification, such as:

- Tracking the device
- Unique serial number
- Unique security key

The UDID comprises five 24-bit program words. When taken together, these fields form a unique 120-bit identifier.

The UDID is stored in five read-only locations, located between 800F00h and 800F08h in the device configuration space. Table 4-1 lists the addresses of the identifier words and shows their contents.

FIGURE 4-4: PROGRAM MEMORY MAP FOR dsPIC33EP128GS70X/80X DEVICES (DUAL PARTITION)

Note: Memory areas are not shown to scale.
4.2.1 PROGRAM MEMORY ORGANIZATION

The program memory space is organized in word-addressable blocks. Although it is treated as 24 bits wide, it is more appropriate to think of each address of the program memory as a lower and upper word, with the upper byte of the upper word being unimplemented. The lower word always has an even address, while the upper word has an odd address (Figure 4-5).

Program memory addresses are always word-aligned on the lower word, and addresses are incremented or decremented by two, during code execution. This arrangement provides compatibility with data memory space addressing and makes data in the program memory space accessible.

4.2.2 INTERRUPT AND TRAP VECTORS

All dsPIC33EPXXXGS70X/80X family devices reserve the addresses between 0x000000 and 0x000200 for hard-coded program execution vectors. A hardware Reset vector is provided to redirect code execution from the default value of the PC on device Reset to the actual start of code. A GOTO instruction is programmed by the user application at address, 0x000000, of Flash memory, with the actual address for the start of code at address, 0x000002, of Flash memory.

A more detailed discussion of the Interrupt Vector Tables (IVTs) is provided in Section 7.1 “Interrupt Vector Table”.

FIGURE 4-5: PROGRAM MEMORY ORGANIZATION
4.3 Data Address Space

The dsPIC33EPXXXGS70X/80X family CPU has a separate 16-bit wide data memory space. The Data Space is accessed using separate Address Generation Units (AGUs) for read and write operations. The data memory map is shown in Figure 4-6.

All Effective Addresses (EAs) in the data memory space are 16 bits wide and point to bytes within the Data Space. This arrangement gives a base Data Space address range of 64 Kbytes or 32K words.

The lower half of the data memory space (i.e., when EA<15> = 0) is used for implemented memory addresses, while the upper half (EA<15> = 1) is reserved for the Program Space Visibility (PSV).

dsPIC33EPXXXGS70X/80X family devices implement up to 12 Kbytes of data memory. If an EA points to a location outside of this area, an all-zero word or byte is returned.

4.3.1 DATA SPACE WIDTH

The data memory space is organized in byte-addressable, 16-bit wide blocks. Data is aligned in data memory and registers as 16-bit words, but all Data Space EAs resolve to bytes. The Least Significant Bytes (LSBs) of each word have even addresses, while the Most Significant Bytes (MSBs) have odd addresses.

4.3.2 DATA MEMORY ORGANIZATION AND ALIGNMENT

To maintain backward compatibility with PIC® MCU devices and improve Data Space memory usage efficiency, the dsPIC33EPXXXGS70X/80X family instruction set supports both word and byte operations. As a consequence of byte accessibility, all Effective Address calculations are internally scaled to step through word-aligned memory. For example, the core recognizes that Post-Modified Register Indirect Addressing mode [Ws++] results in a value of Ws + 1 for byte operations and Ws + 2 for word operations.

A data byte read, reads the complete word that contains the byte, using the LSB of any EA to determine which byte to select. The selected byte is placed onto the LSB of the data path. That is, data memory and registers are organized as two parallel, byte-wide entities with shared (word) address decode, but separate write lines. Data byte writes only write to the corresponding side of the array or register that matches the byte address.

All word accesses must be aligned to an even address. Misaligned word data fetches are not supported, so care must be taken when mixing byte and word operations, or translating from 8-bit MCU code. If a misaligned read or write is attempted, an address error trap is generated. If the error occurred on a read, the instruction underway is completed. If the error occurred on a write, the instruction is executed but the write does not occur. In either case, a trap is then executed, allowing the system and/or user application to examine the machine state prior to execution of the address Fault.

All byte loads into any W register are loaded into the LSB; the MSB is not modified.

A Sign-Extend (SE) instruction is provided to allow user applications to translate 8-bit signed data to 16-bit signed values. Alternatively, for 16-bit unsigned data, user applications can clear the MSB of any W register by executing a Zero-Extend (ZE) instruction on the appropriate address.

4.3.3 SFR SPACE

The first 4 Kbytes of the Near Data Space, from 0x0000 to 0x0FFF, is primarily occupied by Special Function Registers (SFRs). These are used by the dsPIC33EPXXXGS70X/80X family core and peripheral modules for controlling the operation of the device.

SFRs are distributed among the modules that they control and are generally grouped together by module. Much of the SFR space contains unused addresses; these are read as ‘0’.

Note: The actual set of peripheral features and interrupts varies by the device. Refer to the corresponding device tables and pinout diagrams for device-specific information.

4.3.4 NEAR DATA SPACE

The 8-Kbyte area, between 0x0000 and 0x1FFF, is referred to as the Near Data Space. Locations in this space are directly addressable through a 13-bit absolute address field within all memory direct instructions. Additionally, the whole Data Space is addressable using MOV instructions, which support Memory Direct Addressing mode with a 16-bit address field, or by using Indirect Addressing mode using a Working register as an Address Pointer.
FIGURE 4-6: DATA MEMORY MAP FOR dsPIC33EP64GS70X/80X DEVICES

Note: Memory areas are not shown to scale.
4.3.5 X AND Y DATA SPACES

The dsPIC33EPXXXGS70X/80X core has two Data Spaces, X and Y. These Data Spaces can be considered either separate (for some DSP instructions) or as one unified linear address range (for MCU instructions). The Data Spaces are accessed using two Address Generation Units (AGUs) and separate data paths. This feature allows certain instructions to concurrently fetch two words from RAM, thereby enabling efficient execution of DSP algorithms, such as Finite Impulse Response (FIR) filtering and Fast Fourier Transform (FFT).

The X Data Space is used by all instructions and supports all addressing modes. X Data Space has separate read and write data buses. The X read data bus is the read data path for all instructions that view Data Space as combined X and Y address space. It is also the X data prefetch path for the dual operand DSP instructions (MAC class).

The Y Data Space is used in concert with the X Data Space by the MAC class of instructions (CLR, ED, EDAC, MAC, MOVSAC, MPY, MPY.N and MSC) to provide two concurrent data read paths.

Both the X and Y Data Spaces support Modulo Addressing mode for all instructions, subject to addressing mode restrictions. Bit-Reversed Addressing mode is only supported for writes to X Data Space.

All data memory writes, including in DSP instructions, view Data Space as combined X and Y address space. The boundary between the X and Y Data Spaces is device-dependent and is not user-programmable.

4.4 Memory Resources

Many useful resources are provided on the main product page of the Microchip web site for the devices listed in this data sheet. This product page contains the latest updates and additional information.

4.4.1 KEY RESOURCES

Legend: x = unknown or indeterminate value. Address values are in hexadecimal. Reset values are in binary.
The dsPIC33EPXXXGS70X/80X family architecture extends the available Data Space through a paging scheme, which allows the available Data Space to be accessed using MOV instructions in a linear fashion for pre- and post-modified Effective Addresses (EAs). The upper half of the base Data Space address is used in conjunction with the Data Space Read Page (DSRPAG) register to form the Program Space Visibility (PSV) address.

The Data Space Read Page (DSRPAG) register is located in the SFR space. Construction of the PSV address is shown in Figure 4-7. When DSRPAG<9> = 1 and the base address bit, EA<15> = 1, the DSRPAG<8:0> bits are concatenated onto EA<14:0> to form the 24-bit PSV read address.

The paged memory scheme provides access to multiple 32-Kbyte windows in the PSV memory. The Data Space Read Page (DSRPAG) register, in combination with the upper half of the Data Space address, can provide up to 8 Mbytes of PSV address space. The paged data memory space is shown in Figure 4-8.

The Program Space (PS) can be accessed with a DSRPAG of 0x200 or greater. Only reads from PS are supported using the DSRPAG register.

Note: DS read access when DSRPAG = 0x000 will force an address error trap.
FIGURE 4-8: PAGED DATA MEMORY SPACE
When a PSV page overflow or underflow occurs, EA<15> is cleared as a result of the register indirect EA calculation. An overflow or underflow of the EA in the PSV pages can occur at the page boundaries when:

• The initial address, prior to modification, addresses the PSV page
• The EA calculation uses Pre- or Post-Modified Register Indirect Addressing; however, this does not include Register Offset Addressing

In general, when an overflow is detected, the DSRPAG register is incremented and the EA<15> bit is set to keep the base address within the PSV window. When an underflow is detected, the DSRPAG register is decremented and the EA<15> bit is set to keep the base address within the PSV window. This creates a linear PSV address space, but only when using Register Indirect Addressing modes.

Exceptions to the operation described above arise when entering and exiting the boundaries of Page 0 and PSV spaces. Table 4-16 lists the effects of overflow and underflow scenarios at different boundaries.

In the following cases, when overflow or underflow occurs, the EA<15> bit is set and the DSRPAG is not modified; therefore, the EA will wrap to the beginning of the current page:

• Register Indirect with Register Offset Addressing
• Modulo Addressing
• Bit-Reversed Addressing

#### Legend:
- O = Overflow
- U = Underflow
- R = Read
- W = Write

#### Note 1:
- The Register Indirect Addressing now addresses a location in the base Data Space (0x0000-0x7FFF).
- An EDS access, with DSRPAG = 0x000, will generate an address error trap.
- Only reads from PS are supported using DSRPAG.
- Pseudolinear Addressing is not supported for large offsets.
4.5.2 EXTENDED X DATA SPACE

The lower portion of the base address space range, between 0x0000 and 0x7FFF, is always accessible, regardless of the contents of the Data Space Read Page register. It is indirectly addressable through the register indirect instructions. It can be regarded as being located in the default EDS Page 0 (i.e., EDS address range of 0x000000 to 0x007FFF with the base address bit, EA<15> = 0, for this address range). However, Page 0 cannot be accessed through the upper 32 Kbytes, 0x8000 to 0xFFFF, of base Data Space in combination with DSRPAG = 0x00. Consequently, DSRPAG is initialized to 0x001 at Reset.

The remaining PSV pages are only accessible using the DSRPAG register in combination with the upper 32 Kbytes, 0x8000 to 0xFFFF, of the base address, where base address bit, EA<15> = 1.

4.5.3 SOFTWARE STACK

The W15 register serves as a dedicated Software Stack Pointer (SSP), and is automatically modified by exception processing, subroutine calls and returns; however, W15 can be referenced by any instruction in the same manner as all other W registers. This simplifies reading, writing and manipulating the Stack Pointer (for example, creating stack frames).

W15 is initialized to 0x1000 during all Resets. This address ensures that the SSP points to valid RAM in all dsPIC33EPXXXGS70X/80X devices and permits stack availability for non-maskable trap exceptions. These can occur before the SSP is initialized by the user software. You can reprogram the SSP during initialization to any location within Data Space.

The Software Stack Pointer always points to the first available free word and fills the software stack, working from lower toward higher addresses. Figure 4-9 illustrates how it pre-decrements for a stack pop (read) and post-increments for a stack push (writes).

When the PC is pushed onto the stack, PC<15:0> are pushed onto the first available stack word, then PC<22:16> are pushed into the second available stack location. For a PC push during any CALL instruction, the MSB of the PC is zero-extended before the push, as shown in Figure 4-9. During exception processing, the MSB of the PC is concatenated with the lower 8 bits of the CPU STATUS Register, SR. This allows the contents of SRL to be preserved automatically during interrupt processing.

Note 1: To maintain system Stack Pointer (W15) coherency, W15 is never subject to (EDS) paging, and is therefore, restricted to an address range of 0x0000 to 0xFFFF. The same applies to the W14 when used as a Stack Frame Pointer (SFA = 1).

2: As the stack can be placed in, and can access X and Y spaces, care must be taken regarding its use, particularly with regard to local automatic variables in a C development environment.

FIGURE 4-9: CALL STACK FRAME
4.6 Instruction Addressing Modes

The addressing modes shown in Table 4-17 form the basis of the addressing modes optimized to support the specific features of individual instructions. The addressing modes provided in the MAC class of instructions differ from those in the other instruction types.

4.6.1 FILE REGISTER INSTRUCTIONS

Most file register instructions use a 13-bit address field (f) to directly address data present in the first 8192 bytes of data memory (Near Data Space). Most file register instructions employ a Working register, W0, which is denoted as WREG in these instructions. The destination is typically either the same file register or WREG (with the exception of the MUL instruction), which writes the result to a register or register pair. The MOV instruction allows additional flexibility and can access the entire Data Space.

4.6.2 MCU INSTRUCTIONS

The three-operand MCU instructions are of the form:

\[ \text{Operand 3} = \text{Operand 1} \ <\text{function}> \ \text{Operand 2} \]

where Operand 1 is always a Working register (that is, the addressing mode can only be Register Direct), which is referred to as Wb. Operand 2 can be a W register fetched from data memory or a 5-bit literal. The result location can either be a W register or a data memory location. The following addressing modes are supported by MCU instructions:

- Register Direct
- Register Indirect
- Register Indirect Post-Modified
- Register Indirect Pre-Modified
- 5-Bit or 10-Bit Literal

Note: Not all instructions support all the addressing modes given above. Individual instructions can support different subsets of these addressing modes.

4.6.3 MOVE AND ACCUMULATOR INSTRUCTIONS

Move instructions, and the DSP accumulator class of instructions, provide a greater degree of addressing flexibility than other instructions. In addition to the addressing modes supported by most MCU instructions, move and accumulator instructions also support Register Indirect with Register Offset Addressing mode, also referred to as Register Indexed mode.

Note: For the MOV instructions, the addressing mode specified in the instruction can differ for the source and destination EA. However, the 4-bit Wb (Register Offset) field is shared by both source and destination (but typically only used by one).

In summary, the following addressing modes are supported by move and accumulator instructions:

- Register Direct
- Register Indirect
- Register Indirect Post-modified
- Register Indirect Pre-modified
- Register Indirect with Register Offset (Indexed)
- Register Indirect with Literal Offset
- 8-Bit Literal
- 16-Bit Literal

Note: Not all instructions support all the addressing modes given above. Individual instructions may support different subsets of these addressing modes.

4.6.4 MAC INSTRUCTIONS

The dual source operand DSP instructions (CLR, ED, EDAC, MAC, MPY, MPY·N, MOVSAc and MSC), also referred to as MAC instructions, use a simplified set of addressing modes to allow the user application to effectively manipulate the Data Pointers through register indirect tables.

The two-source operand prefetch registers must be members of the set (W8, W9, W10, W11). For data reads, W8 and W9 are always directed to the X RAGU, and W10 and W11 are always directed to the Y AGU. The Effective Addresses generated (before and after modification) must therefore, be valid addresses within X Data Space for W8 and W9, and Y Data Space for W10 and W11.

Note: Register Indirect with Register Offset Addressing mode is available only for W9 (in X space) and W11 (in Y space).

In summary, the following addressing modes are supported by the MAC class of instructions:

- Register Indirect
- Register Indirect Post-Modified by 2
- Register Indirect Post-Modified by 4
- Register Indirect Post-Modified by 6
- Register Indirect with Register Offset (Indexed)

4.6.5 OTHER INSTRUCTIONS

Besides the addressing modes outlined previously, some instructions use literal constants of various sizes. For example, BRA (branch) instructions use 16-bit signed literals to specify the branch destination directly, whereas the DISI instruction uses a 14-bit unsigned literal field. In some instructions, such as ULNK, the source of an operand or result is implied by the opcode itself. Certain operations, such as a NOP, do not have any operands.
4.7 Modulo Addressing

Modulo Addressing mode is a method of providing an automated means to support circular data buffers using hardware. The objective is to remove the need for software to perform data address boundary checks when executing tightly looped code, as is typical in many DSP algorithms.

Modulo Addressing can operate in either Data or Program Space (since the Data Pointer mechanism is essentially the same for both). One circular buffer can be supported in each of the X (which also provides the pointers into Program Space) and Y Data Spaces. Modulo Addressing can operate on any W Register Pointer. However, it is not advisable to use W14 or W15 for Modulo Addressing since these two registers are used as the Stack Frame Pointer and Stack Pointer, respectively.

In general, any particular circular buffer can be configured to operate in only one direction, as there are certain restrictions on the buffer start address (for incrementing buffers) or end address (for decrementing buffers), based upon the direction of the buffer.

The only exception to the usage restrictions is for buffers that have a power-of-two length. As these buffers satisfy the start and end address criteria, they can operate in a Bidirectional mode (that is, address boundary checks are performed on both the lower and upper address boundaries).

### 4.7.1 START AND END ADDRESS

The Modulo Addressing scheme requires that a starting and ending address be specified and loaded into the 16-bit Modulo Buffer Address registers: XMODSRT, XMODEND, YMODSRT and YMODEND (see Table 4-2).

| Note: | Y space Modulo Addressing EA calculations assume word-sized data (LSb of every EA is always clear). |

The length of a circular buffer is not directly specified. It is determined by the difference between the corresponding start and end addresses. The maximum possible length of the circular buffer is 32K words (64 Kbytes).

### 4.7.2 W ADDRESS REGISTER SELECTION

The Modulo and Bit-Reversed Addressing Control register, MODCON<15:0>, contains enable flags, as well as a W register field to specify the W Address registers. The XWM and YWM fields select the registers that operate with Modulo Addressing:

- If XWM = 1111, X RAGU and X WAGU Modulo Addressing is disabled
- If YWM = 1111, Y AGU Modulo Addressing is disabled

The X Address Space Pointer W (XWM) register, to which Modulo Addressing is to be applied, is stored in MODCON<3:0> (see Table 4-2). Modulo Addressing is enabled for X Data Space when XWM is set to any value other than '1111' and the XMODEN bit is set (MODCON<15>).

The Y Address Space Pointer W (YWM) register, to which Modulo Addressing is to be applied, is stored in MODCON<7:4>. Modulo Addressing is enabled for Y Data Space when YWM is set to any value other than '1111' and the YMODEN bit (MODCON<14>) is set.

### FIGURE 4-10: MODULO ADDRESSING OPERATION EXAMPLE

```
| MOV #0x1100, W0      | ;set modulo start address  |
| MOV W0, XMODSRT     | ;set modulo start address  |
| MOV #0x1163, W0      | ;set modulo end address    |
| MOV W0, MODEND      | ;enable W1, X AGU for modulo |
| MOV W0, MODCON      | ;W0 holds buffer fill value |
| MOV #0x0000, W0      | ;point W1 to buffer        |
| MOV #0x1110, W1      | ;fill the 50 buffer locations |
| DO AGAIN, #0x31      | ;fill the next location     |
| MOV W0, [W1++]       | ;increment the fill value   |
```
4.7.3 MODULO ADDRESSING APPLICABILITY

Modulo Addressing can be applied to the Effective Address (EA) calculation associated with any W register. Address boundaries check for addresses equal to:

- The upper boundary addresses for incrementing buffers
- The lower boundary addresses for decrementing buffers

It is important to realize that the address boundaries check for addresses less than or greater than the upper (for incrementing buffers) and lower (for decrementing buffers) boundary addresses (not just equal to). Address changes can, therefore, jump beyond boundaries and still be adjusted correctly.

Note: The modulo corrected Effective Address is written back to the register only when Pre-Modify or Post-Modify Addressing mode is used to compute the Effective Address. When an address offset (such as [W7 + W2]) is used, Modulo Addressing correction is performed, but the contents of the register remain unchanged.

4.8 Bit-Reversed Addressing

Bit-Reversed Addressing mode is intended to simplify data reordering for radix-2 FFT algorithms. It is supported by the X AGU for data writes only.

The modifier, which can be a constant value or register contents, is regarded as having its bit order reversed. The address source and destination are kept in normal order. Thus, the only operand requiring reversal is the modifier.

Note: All bit-reversed EA calculations assume word-sized data (LSb of every EA is always clear). The XB value is scaled accordingly to generate compatible (byte) addresses.

When enabled, Bit-Reversed Addressing is executed only for Register Indirect with Pre-Increment or Post-Increment Addressing and word-sized data writes. It does not function for any other addressing mode or for byte-sized data and normal addresses are generated instead. When Bit-Reversed Addressing is active, the W Address Pointer is always added to the address modifier (XB) and the offset associated with the Register Indirect Addressing mode is ignored. In addition, as word-sized data is a requirement, the LSB of the EA is ignored (and always clear).

Note: Modulo Addressing and Bit-Reversed Addressing can be enabled simultaneously using the same W register, but Bit-Reversed Addressing operation will always take precedence for data writes when enabled.

If Bit-Reversed Addressing has already been enabled by setting the BREN (XBREV<15>) bit, a write to the XBREV register should not be immediately followed by an indirect read operation using the W register that has been designated as the Bit-Reversed Pointer.

4.9 Interfacing Program and Data Memory Spaces

The dsPIC33EPXXXGS70X/80X family architecture uses a 24-bit wide Program Space (PS) and a 16-bit wide Data Space (DS). The architecture is also a modified Harvard scheme, meaning that data can also be present in the Program Space. To use this data successfully, it must be accessed in a way that preserves the alignment of information in both spaces.

Aside from normal execution, the architecture of the dsPIC33EPXXXGS70X/80X family devices provides two methods by which Program Space can be accessed during operation:

- Using table instructions to access individual bytes or words anywhere in the Program Space
- Remapping a portion of the Program Space into the Data Space (Program Space Visibility)

Table instructions allow an application to read or write to small areas of the program memory. This capability makes the method ideal for accessing data tables that need to be updated periodically. It also allows access to all bytes of the program word. The remapping method allows an application to access a large block of data on a read-only basis, which is ideal for look-ups from a large table of static data. The application can only access the least significant word of the program word.

**FIGURE 4-12: DATA ACCESS FROM PROGRAM SPACE ADDRESS GENERATION**

**Note 1:** The Least Significant bit (LSb) of Program Space addresses is always fixed as '0' to maintain word alignment of data in the Program and Data Spaces.

**Note 2:** Table operations are not required to be word-aligned. Table Read operations are permitted in the configuration memory space.
4.9.1 DATA ACCESS FROM PROGRAM MEMORY USING TABLE INSTRUCTIONS

The TBLRDL and TBLWTL instructions offer a direct method of reading or writing the lower word of any address within the Program Space without going through Data Space. The TBLRDH and TBLWTH instructions are the only method to read or write the upper 8 bits of a Program Space word as data.

The PC is incremented by two for each successive 24-bit program word. This allows program memory addresses to directly map to Data Space addresses. Program memory can thus be regarded as two 16-bit wide word address spaces, residing side by side, each with the same address range. TBLRDL and TBLWTL access the space that contains the least significant data word. TBLRDH and TBLWTH access the space that contains the upper data byte.

Two table instructions are provided to move byte or word-sized (16-bit) data to and from Program Space. Both function as either byte or word operations.

- **TBLRDL (Table Read Low):**
  - In Word mode, this instruction maps the lower word of the Program Space location (P<15:0>) to a data address (D<15:0>).
  - In Byte mode, either the upper or lower byte of the lower program word is mapped to the lower byte of a data address. The upper byte is selected when Byte Select is '1'; the lower byte is selected when it is '0'.

- **TBLRDH (Table Read High):**
  - In Word mode, this instruction maps the entire upper word of a program address (P<23:16>) to a data address. The 'phantom' byte (D<15:8>) is always '0'.
  - In Byte mode, this instruction maps the upper or lower byte of the program word to D<7:0> of the data address in the TBLRDL instruction. The data is always '0' when the upper 'phantom' byte is selected (Byte Select = 1).

In a similar fashion, two table instructions, TBLWTH and TBLWTL, are used to write individual bytes or words to a Program Space address. The details of their operation are explained in Section 5.0 “Flash Program Memory”.

For all table operations, the area of program memory space to be accessed is determined by the Table Page register (TBLPAG). TBLPAG covers the entire program memory space of the device, including user application and configuration spaces. When TBLPAG<7> = 0, the table page is located in the user memory space. When TBLPAG<7> = 1, the page is located in configuration space.

**FIGURE 4-13: ACCESSING PROGRAM MEMORY WITH TABLE INSTRUCTIONS**

The address for the table operation is determined by the data EA within the page defined by the TBLPAG register. Only read operations are shown; write operations are also valid in the user memory area.
5.0 FLASH PROGRAM MEMORY

Note 1: This data sheet summarizes the features of the dsPIC33EPXXXGS70X/80X family of devices. It is not intended to be a comprehensive reference source. To complement the information in this data sheet, refer to “Dual Partition Flash Program Memory” (DS70005156) in the “dsPIC33/PIC24 Family Reference Manual”, which is available from the Microchip web site (www.microchip.com)

2: Some registers and associated bits described in this section may not be available on all devices. Refer to Section 4.0 “Memory Organization” in this data sheet for device-specific register and bit information.

The dsPIC33EPXXXGS70X/80X family devices contain internal Program Flash Memory for storing and executing application code. The memory is readable, writable and erasable during normal operation over the entire VDD range.

Flash memory can be programmed in three ways:

- In-Circuit Serial Programming™ (ICSP™) programming capability
- Enhanced In-Circuit Serial Programming (Enhanced ICSP)
- Run-Time Self-Programming (RTSP)

ICSP allows for a dsPIC33EPXXXGS70X/80X family device to be serially programmed while in the end application circuit. This is done with a programming clock and programming data (PGECx/PGEDx) line, and three other lines for power (VDD), ground (VSS) and Master Clear (MCLR). This allows customers to manufacture boards with unprogrammed devices and then program the device just before shipping the product. This also allows the most recent firmware or a custom firmware to be programmed.

Enhanced In-Circuit Serial Programming uses an on-board bootloader, known as the Program Executive, to manage the programming process. Using an SPI data frame format, the Program Executive can erase, program and verify program memory. For more information on Enhanced ICSP, see the device programming specification.

RTSP is accomplished using TBLRD (Table Read) and TBLWT (Table Write) instructions. With RTSP, the user application can write program memory data with a single program memory word and erase program memory in blocks or ‘pages’ of 512 instructions (1536 bytes) at a time.

5.1 Table Instructions and Flash Programming

Regardless of the method used, all programming of Flash memory is done with the Table Read and Table Write instructions. These instructions allow direct read and write access to the program memory space, from the data memory, while the device is in normal operating mode. The 24-bit target address in the program memory is formed using bits<7:0> of the TBLPAG register and the Effective Address (EA) from a W register, specified in the table instruction, as shown in Figure 5-1. The TBLRD and the TBLWT instructions are used to read or write to bits<15:0> of program memory. TBLRD and TBLWT can access program memory in both Word and Byte modes. The TBLRDH and TBLWTH instructions are used to read or write to bits<23:16> of program memory. TBLRDH and TBLWTH can also access program memory in Word or Byte mode.

FIGURE 5-1: ADDRESSING FOR TABLE REGISTERS

![Diagram of addressing for table registers]
5.2 RTSP Operation

The dsPIC33EPXXXGS70X/80X family Flash program memory array is organized into rows of 64 instructions or 192 bytes. RTSP allows the user application to erase a single page (8 rows or 512 instructions) of memory at a time and to program one row at a time. It is possible to program two instructions at a time as well.

The page erase and single row write blocks are edge-aligned, from the beginning of program memory, on boundaries of 1536 bytes and 192 bytes, respectively. Figure 30-14 in Section 30.0 “Electrical Characteristics” lists the typical erase and programming times.

Row programming is performed by loading 192 bytes into data memory and then loading the address of the first byte in that row into the NVMSRCADR register. Once the write has been initiated, the device will automatically load the write latches and increment the NVMSRCADR and the NVMADR(U) registers until all bytes have been programmed. The RPDF bit (NVMCON<9>) selects the format of the stored data in RAM to be either compressed or uncompressed. See Figure 5-2 for data formatting. Compressed data helps to reduce the amount of required RAM by using the upper byte of the second word for the MSB of the second instruction.

The basic sequence for RTSP word programming is to use the TBLWTL and TBLWTH instructions to load two of the 24-bit instructions into the write latches found in configuration memory space. Refer to Figure 4-1 through Figure 4-4 for write latch addresses. Programming is performed by unlocking and setting the control bits in the NVMCON register.

All erase and program operations may optionally use the NVM interrupt to signal the successful completion of the operation. For example, when performing Flash write operations on the Inactive Partition in Dual Partition mode, where the CPU remains running, it is necessary to wait for the NVM interrupt before programming the next block of Flash program memory.

5.3 Programming Operations

A complete programming sequence is necessary for programming or erasing the internal Flash in RTSP mode. The processor stalls (waits) until the programming operation is finished. Setting the WR bit (NVMCON<15>) starts the operation and the WR bit is automatically cleared when the operation is finished.

5.3.1 PROGRAMMING ALGORITHM FOR FLASH PROGRAM MEMORY

Programmers can program two adjacent words (24 bits x 2) of Program Flash Memory at a time on every other word address boundary (0x000000, 0x000004, 0x000008, etc.). To do this, it is necessary to erase the page that contains the desired address of the location the user wants to change. For protection against accidental operations, the write initiate sequence for NVMKEY must be used to allow any erase or program operation to proceed. After the programming command has been executed, the user application must wait for the programming time until programming is complete. The two instructions following the start of the programming sequence should be NOPs.
5.4 Dual Partition Flash Configuration

For dsPIC33EPXXXGS70X/80X devices operating in Dual Partition Flash Program Memory modes, the Inactive Partition can be erased and programmed without stalling the processor. The same programming algorithms are used for programming and erasing the Flash in the Inactive Partition, as described in Section 5.2 “RTSP Operation”. On top of the page erase option, the entire Flash memory of the Inactive Partition can be erased by configuring the NVMOP<3:0> bits in the NVMCON register.

Note 1: The application software to be loaded into the Inactive Partition will have the address of the Active Partition. The bootloader firmware will need to offset the address by 0x400000 in order to write to the Inactive Partition.

5.4.1 FLASH PARTITION SWAPPING

The Boot Sequence Number is used for determining the Active Partition at start-up and is encoded within the FBTSEQ Configuration register bits. Unlike most Configuration registers, which only utilize the lower 16 bits of the program memory, FBTSEQ is a 24-bit Configuration Word. The Boot Sequence Number (BSEQ) is a 12-bit value and is stored in FBTSEQ twice. The true value is stored in bits, FBTSEQ<11:0>, and its complement is stored in bits, FBTSEQ<23:12>. At device Reset, the sequence numbers are read and the partition with the lowest sequence number becomes the Active Partition. If one of the Boot Sequence Numbers is invalid, the device will select the partition with the valid Boot Sequence Number, or default to Partition 1 if both sequence numbers are invalid. See Section 27.0 “Special Features” for more information.

The BOOTSWP instruction provides an alternative means of swapping the Active and Inactive Partitions (soft swap) without the need for a device Reset. The BOOTSWP must always be followed by a GOTO instruction. The BOOTSWP instruction swaps the Active and Inactive Partitions, and the PC vectors to the location specified by the GOTO instruction in the newly Active Partition.

It is important to note that interrupts should temporarily be disabled while performing the soft swap sequence and that after the partition swap, all peripherals and interrupts which were enabled remain enabled. Additionally, the RAM and stack will maintain state after the switch. As a result, it is recommended that applications using soft swaps jump to a routine that will reinitialize the device in order to ensure the firmware runs as expected. The Configuration registers will have no effect during a soft swap.

For robustness of operation, in order to execute the BOOTSWP instruction, it is necessary to execute the NVM unlocking sequence as follows:

1. Write 0x55 to NVMKEY.
2. Write 0xAA to NVMKEY.
3. Execute the BOOTSWP instruction.

If the unlocking sequence is not performed, the BOOTSWP instruction will be executed as a forced NOP and a GOTO instruction, following the BOOTSWP instruction, will be executed, causing the PC to jump to that location in the current operating partition.

The SFTSWP and P2ACTIV bits in the NVMCON register are used to determine a successful swap of the Active and Inactive Partitions, as well as which partition is active. After the BOOTSWP and GOTO instructions, the SFTSWP bit should be polled to verify the partition swap has occurred and then cleared for the next panel swap event.

5.4.2 DUAL PARTITION MODES

While operating in Dual Partition mode, the dsPIC33EPXXXGS70X/80X family devices have the option for both partitions to have their own defined security segments, as shown in Figure 27-4. Alternatively, the device can operate in Protected Dual Partition mode, where Partition 1 becomes permanently erase/write-protected. Protected Dual Partition mode allows for a “Factory Default” mode, which provides a fail-safe backup image to be stored in Partition 1.

dsPIC33EPXXXGS70X/80X family devices can also operate in Privileged Dual Partition mode, where additional security protections are implemented to allow for protection of intellectual property when multiple parties have software within the device. In Privileged Dual Partition mode, both partitions place additional restrictions on the FBSLIM register. These prevent changes to the size of the Boot Segment and General Segment, ensuring that neither segment will be altered.

5.5 Flash Memory Resources

Many useful resources are provided on the main product page of the Microchip web site for the devices listed in this data sheet. This product page contains the latest updates and additional information.

5.5.1 KEY RESOURCES

5.6 Control Registers

Five SFRs are used to write and erase the Program Flash Memory: NVMCON, NVMKEY, NVMADR, NVMADRU and NVMSRCADR/H.

The NVMCON register (Register 5-1) selects the operation to be performed (page erase, word/row program, Inactive Partition erase), initiates the program or erase cycle and is used to determine the Active Partition in Dual Partition modes.

NVMKEY (Register 5-4) is a write-only register that is used for write protection. To start a programming or erase sequence, the user application must consecutively write 0x55 and 0xAA to the NVMKEY register.

There are two NVM Address registers: NVMADRU and NVMADR. These two registers, when concatenated, form the 24-bit Effective Address (EA) of the selected word/row for programming operations, or the selected page for erase operations. The NVMADRU register is used to hold the upper 8 bits of the EA, while the NVMADR register is used to hold the lower 16 bits of the EA.

For row programming operation, data to be written to Program Flash Memory is written into data memory space (RAM) at an address defined by the NVMSRCADR register (location of first element in row programming data).

- **WRERR**: Write Sequence Error Flag bit
  - 1 = An improper program or erase sequence attempt, or termination has occurred (bit is set automatically on any set attempt of the WR bit)
  - 0 = The program or erase operation completed normally

**bit 12**
- **NVMSIDL**: NVM Stop in Idle Control bit
  - 1 = Flash voltage regulator goes into Standby mode during Idle mode
  - 0 = Flash voltage regulator is active during Idle mode

**bit 11**
- **SFTSWP**: Partition Soft Swap Status bit
  - 1 = Partitions have been successfully swapped using the **BOOTSWP** instruction (soft swap)
  - 0 = Awaiting successful partition swap using the **BOOTSWP** instruction or a device Reset will determine the Active Partition based on the FBTSEQ register

**bit 10**
- **P2ACTIV**: Partition 2 Active Status bit
  - 1 = Partition 2 Flash is mapped into the active region
  - 0 = Partition 1 Flash is mapped into the active region

**bit 9**
- **RPDF**: Row Programming Data Format bit
  - 1 = Row data to be stored in RAM is in compressed format
  - 0 = Row data to be stored in RAM is in uncompressed format

**bit 8**
- **URERR**: Row Programming Data Underrun Error bit
  - 1 = Indicates row programming operation has been terminated
  - 0 = No data underrun error is detected

**bit 7-4**
- Unimplemented: Read as ‘0’

**Note 1:** These bits can only be reset on a POR.
- **2:** If this bit is set, power consumption will be further reduced (IIDLE) and upon exiting Idle mode, there is a delay (TVREG) before Flash memory becomes operational.
- **3:** All other combinations of NVMOP<3:0> are unimplemented.
- **4:** Execution of the **PWRSAV** instruction is ignored while any of the NVM operations are in progress.
- **5:** Two adjacent words on a 4-word boundary are programmed during execution of this operation.
- **6:** Only applicable when operating in Dual Partition mode.

**NVMSRCADR<15:0>:** NVM Source Data Address bits

The RAM address of the data to be programmed into Flash when the NVMOP<3:0> bits are set to row programming.
6.0 RESETS

The Reset module combines all Reset sources and controls the device Master Reset Signal, SYSRST. The following is a list of device Reset sources:

- POR: Power-on Reset
- BOR: Brown-out Reset
- MCLR: Master Clear Pin Reset
- SWR: RESET Instruction
- WDTO: Watchdog Timer Time-out Reset
- CM: Configuration Mismatch Reset
- TRAPR: Trap Conflict Reset
- IOPUWR: Illegal Condition Device Reset
  - Illegal Opcode Reset
  - Uninitialized W Register Reset
  - Security Reset

A simplified block diagram of the Reset module is shown in Figure 6-1.

Any active source of Reset will make the SYSRST signal active. On system Reset, some of the registers associated with the CPU and peripherals are forced to a known Reset state, and some are unaffected.

All types of device Reset set a corresponding status bit in the RCON register to indicate the type of Reset (see Register 6-1).

A POR clears all the bits, except for the BOR and POR bits (RCON<1:0>) that are set. The user application can set or clear any bit, at any time, during code execution. The RCON bits only serve as status bits. Setting a particular Reset status bit in software does not cause a device Reset to occur.

The RCON register also has other bits associated with the Watchdog Timer and device power-saving states. The function of these bits is discussed in other sections of this manual.

For all Resets, the default clock source is determined by the FNOSC<2:0> bits in the FOSCSEL Configuration register. The value of the FNOSC<2:0> bits is loaded into the OSCON<10:8> (OSCCON<10:8>) bits on Reset, which in turn, initializes the system clock.
6.1 Reset Resources

Many useful resources are provided on the main product page of the Microchip web site for the devices listed in this data sheet. This product page contains the latest updates and additional information.

6.1.1 KEY RESOURCES

• “Reset” (DS70602) in the “dsPIC33/PIC24 Family Reference Manual”
• Code Samples
• Application Notes
• Software Libraries
• Webinars
• All Related “dsPIC33/PIC24 Family Reference Manual” Sections
• Development Tools

**Note 2:** If the WDTEN<1:0> Configuration bits are ‘11’ (unprogrammed), the WDT is always enabled, regardless of the SWDTEN bit setting.
7.0 INTERRUPT CONTROLLER

The dsPIC33EPXXXGS70X/80X family interrupt controller reduces the numerous peripheral interrupt request signals to a single interrupt request signal to the dsPIC33EPXXXGS70X/80X family CPU.

The interrupt controller has the following features:

- Six Processor Exceptions and Software Traps
- Seven User-Selectable Priority Levels
- Interrupt Vector Table (IVT) with a Unique Vector for each Interrupt or Exception Source
- Fixed Priority within a Specified User Priority Level
- Fixed Interrupt Entry and Return Latencies
- Alternate Interrupt Vector Table (AIVT) for Debug Support

7.1 Interrupt Vector Table

The dsPIC33EPXXXGS70X/80X family Interrupt Vector Table (IVT), shown in Figure 7-1, resides in program memory, starting at location 000000h. The IVT contains six non-maskable trap vectors and up to 246 sources of interrupts. In general, each interrupt source has its own vector. Each interrupt vector contains a 24-bit wide address. The value programmed into each interrupt vector location is the starting address of the associated Interrupt Service Routine (ISR).

Interrupt vectors are prioritized in terms of their natural priority. This priority is linked to their position in the vector table. Lower addresses generally have a higher natural priority. For example, the interrupt associated with Vector 0 takes priority over interrupts at any other vector address.

7.1.1 ALTERNATE INTERRUPT VECTOR TABLE

The Alternate Interrupt Vector Table (AIVT), shown in Figure 7-2, is available only when the Boot Segment is defined and the AIVT has been enabled. To enable the Alternate Interrupt Vector Table, the Configuration bit, AIVTDIS in the FSEC register, must be programmed and the AIVTEN bit must be set (INTCON2<8> = 1). When the AIVT is enabled, all interrupt and exception processes use the alternate vectors instead of the default vectors. The AIVT begins at the start of the last page of the Boot Segment, defined by BSLIM<12:0>. The second half of the page is no longer usable space. The Boot Segment must be at least 2 pages to enable the AIVT.

The AIVT supports debugging by providing a means to switch between an application and a support environment without requiring the interrupt vectors to be reprogrammed. This feature also enables switching between applications for evaluation of different software algorithms at run time.

7.2 Reset Sequence

A device Reset is not a true exception because the interrupt controller is not involved in the Reset process. The dsPIC33EPXXXGS70X/80X family devices clear their registers in response to a Reset, which forces the PC to zero. The device then begins program execution at location, 0x000000. A GOTO instruction at the Reset address can redirect program execution to the appropriate start-up routine.

Note: Any unimplemented or unused vector locations in the IVT should be programmed with the address of a default interrupt handler routine that contains a RESET instruction.

dsPIC33EPXXXGS70X/80X FAMILY

7.3 Interrupt Resources

Many useful resources are provided on the main product page of the Microchip web site for the devices listed in this data sheet. This product page contains the latest updates and additional information.

7.3.1 KEY RESOURCES

- "Interrupts" (DS70000600) in the "dsPIC33/PIC24 Family Reference Manual"
- Code Samples
- Application Notes
- Software Libraries
- Webinars
- All Related “dsPIC33/PIC24 Family Reference Manual” Sections
- Development Tools

7.4 Interrupt Control and Status Registers

dspIC33EPXXXGS70X/80X family devices implement the following registers for the interrupt controller:

- INTCON1
- INTCON2
- INTCON3
- INTCON4
- INTTREG

7.4.1 INTCON1 THROUGH INTCON4

Global interrupt control functions are controlled from INTCON1, INTCON2, INTCON3 and INTCON4.

INTCON1 contains the Interrupt Nesting Disable bit (NSTDIS), as well as the control and status flags for the processor trap sources.

The INTCON2 register controls external interrupt request signal behavior, contains the Global Interrupt Enable bit (GIE) and the Alternate Interrupt Vector Table Enable bit (AIVTEN).

INTCON3 contains the status flags for the Auxiliary PLL and do stack overflow status trap sources.

The INTCON4 register contains the Software Generated Hard Trap Status bit (SGHT).

7.4.2 IFSx

The IFSx registers maintain all of the interrupt request flags. Each source of interrupt has a status bit, which is set by the respective peripherals or external signal and is cleared via software.

7.4.3 IECx

The IECx registers maintain all of the interrupt enable bits. These control bits are used to individually enable interrupts from the peripherals or external signals.

7.4.4 IPCx

The IPCx registers are used to set the Interrupt Priority Level (IPL) for each source of interrupt. Each user interrupt source can be assigned to one of seven priority levels.

7.4.5 INTTREG

The INTTREG register contains the associated interrupt vector number and the new CPU Interrupt Priority Level, which are latched into the Vector Number of Pending Interrupt bits (VECNUM<7:0>) and New CPU Interrupt Priority Level bits (ILR<3:0>) fields in the INTTREG register. The new Interrupt Priority Level is the priority of the pending interrupt.

The interrupt sources are assigned to the IFSx, IECx and IPCx registers in the same sequence as they are listed in Table 7-1. For example, the INT0 (External Interrupt 0) is shown as having Vector Number 8 and a natural order priority of 0. Thus, the INT0IF bit is found in IFS0<0>, the INT0IE bit in IEC0<0> and the INT0IP<2:0> bits in the first position of IPC0 (IPC0<2:0>).

7.4.6 STATUS/CONTROL REGISTERS

Although these registers are not specifically part of the interrupt control hardware, two of the CPU Control registers contain bits that control interrupt functionality. For more information on these registers, refer to “dsPIC33E Enhanced CPU” (DS70005158) in the “dsPIC33/PIC24 Family Reference Manual”.

- The CPU STATUS Register, SR, contains the IPL<2:0> bits (SR<7:5>). These bits indicate the current CPU Interrupt Priority Level. The user software can change the current CPU Interrupt Priority Level by writing to the IPLx bits.
- The CORCON register contains the IPL3 bit which, together with IPL<2:0>, also indicates the current CPU priority level. IPL3 is a read-only bit so that trap events cannot be masked by the user software.

All Interrupt registers are described in Register 7-3 through Register 7-7 in the following pages.
REGISTER 7-1: SR: CPU STATUS REGISTER(1)

bit 7-5

**IPL<2:0>: CPU Interrupt Priority Level Status bits(2,3)**

- 111 = CPU Interrupt Priority Level is 7 (15); user interrupts are disabled
- 110 = CPU Interrupt Priority Level is 6 (14)
- 101 = CPU Interrupt Priority Level is 5 (13)
- 100 = CPU Interrupt Priority Level is 4 (12)
- 011 = CPU Interrupt Priority Level is 3 (11)
- 010 = CPU Interrupt Priority Level is 2 (10)
- 001 = CPU Interrupt Priority Level is 1 (9)
- 000 = CPU Interrupt Priority Level is 0 (8)

Note 1: For complete register details, see Register 3-1.

2: The IPL<2:0> bits are concatenated with the IPL<3> bit (CORCON<3>) to form the CPU Interrupt Priority Level. The value in parentheses indicates the IPL, if IPL<3> = 1. User interrupts are disabled when IPL<3> = 1.

3: The IPL<2:0> Status bits are read-only when the NSTDIS bit (INTCON1<15>) = 1.
## REGISTER 7-2: CORCON: CORE CONTROL REGISTER(1)

- 00000000 = 0, Oscillator fail trap
8.0 DIRECT MEMORY ACCESS (DMA)

The DMA Controller transfers data between Peripheral Data registers and Data Space SRAM. In addition, DMA can access the entire data memory space. The data memory bus arbiter is utilized when either the CPU or DMA attempts to access SRAM, resulting in potential DMA or CPU Stalls.

The DMA Controller supports 4 independent channels. Each channel can be configured for transfers to or from selected peripherals. The peripherals supported by the DMA Controller include:

- CAN
- UART
- Input Capture
- Output Compare
- Timers

Refer to Table 8-1 for a complete list of supported peripherals.

Note 1: This data sheet summarizes the features of the dsPIC33EPXXXGS70X/80X family of devices. It is not intended to be a comprehensive reference source. To complement the information in this data sheet, refer to “Direct Memory Access (DMA)” (DS70348) in the “dsPIC33/PIC24 Family Reference Manual”, which is available from the Microchip web site (www.microchip.com).

2: Some registers and associated bits described in this section may not be available on all devices. Refer to Section 4.0 “Memory Organization” in this data sheet for device-specific register and bit information.

FIGURE 8-1: PERIPHERAL TO DMA CONTROLLER

![Diagram of Peripheral to DMA Controller](see Figure 4-10)
In addition, DMA transfers can be triggered by timers as well as external interrupts. Each DMA channel is unidirectional. Two DMA channels must be allocated to read and write to a peripheral. If more than one channel receives a request to transfer data, a simple fixed priority scheme, based on channel number, dictates which channel completes the transfer and which channel, or channels, are left pending. Each DMA channel moves a block of data, after which, it generates an interrupt to the CPU to indicate that the block is available for processing.

The DMA Controller provides these functional capabilities:
- Four DMA Channels
- Register Indirect with Post-Increment Addressing mode
- Register Indirect without Post-Increment Addressing mode
- Peripheral Indirect Addressing mode (peripheral generates destination address)
- CPU Interrupt after Half or Full Block Transfer Complete
- Byte or Word Transfers
- Fixed Priority Channel Arbitration
- Manual (software) or Automatic (peripheral DMA requests) Transfer Initiation
- One-Shot or Auto-Repeat Block Transfer modes
- Ping-Pong mode (automatic switch between two SRAM Start addresses after each block transfer complete)
- DMA Request for each Channel can be Selected from any Supported Interrupt Source
- Debug Support Features

The peripherals that can utilize DMA are listed in Table 8-1.

FIGURE 8-2: DMA CONTROLLER BLOCK DIAGRAM

Note: CPU and DMA address buses are not shown for clarity.
8.1 DMA Controller Registers

Each DMA Controller Channel x (where x = 0 through 3) contains the following registers:

- 16-Bit DMA Channel x Control Register (DMAxCON)
- 16-Bit DMA Channel x IRQ Select Register (DMAxREQ)
- 32-Bit DMA Channel x Start Address Register A (DMAxSTAL/H)
- 32-Bit DMA Channel x Start Address Register B (DMAxSTBL/H)
- 16-Bit DMA Channel x Peripheral Address Register (DMAxPAD)
- 14-Bit DMA Channel x Transfer Count Register (DMAxCNT)

Additional status registers (DMAPWC, DMARQC, DMAPPS, DMALCA and DSADRL/H) are common to all DMA Controller channels. These status registers provide information on write and request collisions, as well as on last address and channel access information.

The interrupt flags (DMAxF) are located in an IFSx register in the interrupt controller. The corresponding interrupt enable control bits (DMAxE) are located in an IECx register in the interrupt controller and the corresponding interrupt priority control bits (DMAxP) are located in an IPCx register in the interrupt controller.

9.0 OSCILLATOR CONFIGURATION

The dsPIC33EPXXXGS70X/80X family oscillator system provides:

- On-Chip Phase-Locked Loop (PLL) to Boost Internal Operating Frequency on Select Internal and External Oscillator Sources
- On-the-Fly Clock Switching between Various Clock Sources
- Doze mode for System Power Savings
- Fail-Safe Clock Monitor (FSCM) that Detects Clock Failure and Permits Safe Application Recovery or Shutdown
- Configuration Bits for Clock Source Selection
- Auxiliary PLL for ADC and PWM

A simplified diagram of the oscillator system is shown in Figure 9-1.

Note 1: This data sheet summarizes the features of the dsPIC33EPXXXGS70X/80X family of devices. It is not intended to be a comprehensive reference source. To complement the information in this data sheet, refer to “Oscillator Module” (DS70005131) in the “dsPIC33/PIC24 Family Reference Manual”, which is available from the Microchip web site (www.microchip.com).

2: Some registers and associated bits described in this section may not be available on all devices. Refer to Section 4.0 “Memory Organization” in this data sheet for device-specific register and bit information.
FIGURE 9-1: OSCILLATOR SYSTEM DIAGRAM

Note 1: See Figure 9-2 for the source of the Fvco signal.
2: FP refers to the clock source for all the peripherals, while FCY (or MIPS) refers to the clock source for the CPU. Throughout this document, FCY and FP are used interchangeably, except in the case of Doze mode. FP and FCY will be different when Doze mode is used in any ratio other than 1:1.
3: The auxiliary clock postscaler must be configured to divide-by-1 (APSTSCLR<2:0> = 111) for proper operation of the PWM and ADC modules.
9.1 CPU Clocking System

The dsPIC33EPXXXGS70X/80X family of devices provides six system clock options:

- Fast RC (FRC) Oscillator
- FRC Oscillator with Phase-Locked Loop (FRCPLL)
- FRC Oscillator with Postscaler
- Primary (XT, HS or EC) Oscillator
- Primary Oscillator with PLL (XTPLL, HSPLL, ECPLL)
- Low-Power RC (LPRC) Oscillator

Instruction execution speed or device operating frequency, FCY, is given by Equation 9-1.

**EQUATION 9-1: DEVICE OPERATING FREQUENCY**

\[
FCY = \frac{F_{osc}}{2}
\]

Figure 9-2 is a block diagram of the PLL module. Equation 9-2 provides the relationship between Input Frequency (Fin) and Output Frequency (FPLLO). Equation 9-3 provides the relationship between Input Frequency (Fin) and VCO Frequency (FVCO).

**FIGURE 9-2: PLL BLOCK DIAGRAM**

Note 1: This frequency range must be met at all times.

**EQUATION 9-2: FPLLO CALCULATION**

\[
F_{PLLO} = \text{Fin} \times \left( \frac{M}{N_1 \times N_2} \right) = \text{Fin} \times \left( \frac{PLL DIV{<8:0>}}{(PLL PRE{<4:0>} + 2)(PLL POST{<1:0>} + 1)} \right)
\]

Where:

- \(N_1 = \text{PLL PRE}{<4:0>} + 2\)
- \(N_2 = 2 \times (\text{PLL POST}{<1:0>} + 1)\)
- \(M = \text{PLL DIV}{<8:0>} + 2\)

**EQUATION 9-3: FVCO CALCULATION**

\[
F_{VCO} = \text{Fin} \times \left( \frac{M}{N_1} \right) = \text{Fin} \times \left( \frac{PLL DIV{<8:0>}}{(PLL PRE{<4:0>} + 2)} \right)
\]

</tbody>
</table>

Note 1: OSC2 pin function is determined by the OSCIOFNC Configuration bit.
Note 2: This is the default Oscillator mode for an unprogrammed (erased) device.

9.2 Auxiliary Clock Generation

The auxiliary clock generation is used for peripherals that need to operate at a frequency unrelated to the system clock, such as PWM or ADC.

The primary oscillator and internal FRC oscillator sources can be used with an Auxiliary PLL (APLL) to obtain the auxiliary clock. The Auxiliary PLL has a fixed 16x multiplication factor.

The auxiliary clock has the following configuration restrictions:

• For proper PWM operation, auxiliary clock generation must be configured for 120 MHz (see Parameter OS56 in Section 30.0 “Electrical Characteristics”). If a slower frequency is desired, the PWM Input Clock Prescaler (Divider) Select bits (PCLKDIV<2:0>) should be used.
• To achieve 1.04 ns PWM resolution, the auxiliary clock must use the 16x Auxiliary PLL (APLL). All other clock sources will have a minimum PWM resolution of 8 ns.
• If the primary PLL is used as a source for the auxiliary clock, the primary PLL should be configured up to a maximum operation of 30 MIPS or less.

9.3 Reference Clock Generation

The reference clock output logic provides the user with the ability to output a clock signal based on the system clock or the crystal oscillator on a device pin. The user application can specify a wide range of clock scaling prior to outputting the reference clock.

9.4 Oscillator Resources

Many useful resources are provided on the main product page of the Microchip web site for the devices listed in this data sheet. This product page contains the latest updates and additional information.

9.4.1 KEY RESOURCES

• “Oscillator Module” (DS70005131) in the “dsPIC33/PIC24 Family Reference Manual”
• Code Samples
• Application Notes
• Software Libraries
• Webinars
• All Related “dsPIC33/PIC24 Family Reference Manual” Sections
• Development Tools

| 01 | Primary Oscillator (XT, HS, EC) |
| 00 | Fast RC Oscillator (FRC) with Divide-by-N and PLL (FRCPLL) |
| 00 | Fast RC Oscillator (FRC) |

| bit 7 |
| CLKLOCK: Clock Lock Enable bit |
| 1 | If (FCKSM0 = 1), then clock and PLL configurations are locked; if (FCKSM0 = 0), then clock and PLL configurations may be modified |
| 0 | Clock and PLL selections are not locked, configurations may be modified |

| bit 6 |
| IOLOCK: I/O Lock Enable bit |
| 1 | I/O lock is active |
| 0 | I/O lock is not active |

| bit 5 |
| LOCK: PLL Lock Status bit (read-only) |
| 1 | Indicates that PLL is in lock or PLL start-up timer is satisfied |
| 0 | Indicates that PLL is out of lock, start-up timer is in progress or PLL is disabled |

**Legend:**

- y = Value set from Configuration bits on POR
- R = Readable bit
- W = Writable bit
- U = Unimplemented bit, read as ‘0’
- -n = Value at POR
- ‘1’ = Bit is set
- ‘0’ = Bit is cleared
- x = Bit is unknown

---

**Note 1:** Writes to this register require an unlock sequence.

**Note 2:** Direct clock switches between any Primary Oscillator mode with PLL and FRCPLL mode are not permitted. This applies to clock switches in either direction. In these instances, the application must switch to FRC mode as a transitional clock source between the two PLL modes.

**Note 3:** This bit should only be cleared in software. Setting the bit in software (\(= 1\)) will have the same effect as an actual oscillator failure and will trigger an oscillator failure trap.
REGISTER 9-1:  OSCCON: OSCILLATOR CONTROL REGISTER\(^{(1)}\) (CONTINUED)

10.0 POWER-SAVING FEATURES

The dsPIC33EPXXXGS70X/80X family devices provide the ability to manage power consumption by selectively managing clocking to the CPU and the peripherals. In general, a lower clock frequency and a reduction in the number of peripherals being clocked constitutes lower consumed power.

dsPIC33EPXXXGS70X/80X family devices can manage power consumption in four ways:

- Clock Frequency
- Instruction-Based Sleep and Idle modes
- Software-Controlled Doze mode
- Selective Peripheral Control in Software

Combinations of these methods can be used to selectively tailor an application’s power consumption while still maintaining critical application features, such as timing-sensitive communications.

EXAMPLE 10-1: PWRSAV INSTRUCTION SYNTAX

```
PWRSAV #SLEEP_MODE ; Put the device into Sleep mode
PWRSAV #IDLE_MODE ; Put the device into Idle mode
```

Note 1: This data sheet summarizes the features of the dsPIC33EPXXXGS70X/80X family of devices. It is not intended to be a comprehensive reference source. To complement the information in this data sheet, refer to “Watchdog Timer and Power-Saving Modes” (DS70615) in the “dsPIC33/PIC24 Family Reference Manual”, which is available from the Microchip web site (www.microchip.com).

2: Some registers and associated bits described in this section may not be available on all devices. Refer to Section 4.0 “Memory Organization” in this data sheet for device-specific register and bit information.

10.1 Clock Frequency and Clock Switching

The dsPIC33EPXXXGS70X/80X family devices allow a wide range of clock frequencies to be selected under application control. If the system clock configuration is not locked, users can choose low-power or high-precision oscillators by simply changing the NOSCx bits (OSCCON<10:8>). The process of changing a system clock during operation, as well as limitations to the process, are discussed in more detail in Section 9.0 “Oscillator Configuration”.

10.2 Instruction-Based Power-Saving Modes

The dsPIC33EPXXXGS70X/80X family devices have two special power-saving modes that are entered through the execution of a special PWRSAV instruction. Sleep mode stops clock operation and halts all code execution. Idle mode halts the CPU and code execution, but allows peripheral modules to continue operation. The assembler syntax of the PWRSAV instruction is shown in Example 10-1.

```
PWRSAV #SLEEP_MODE ; Put the device into Sleep mode
PWRSAV #IDLE_MODE ; Put the device into Idle mode
```

Note: SLEEP_MODE and IDLE_MODE are constants defined in the assembler include file for the selected device.

Sleep and Idle modes can be exited as a result of an enabled interrupt, WDT time-out or a device Reset. When the device exits these modes, it is said to “wake-up.”
10.2.1 SLEEP MODE
The following occurs in Sleep mode:

- The system clock source is shut down. If an on-chip oscillator is used, it is turned off.
- The device current consumption is reduced to a minimum, provided that no I/O pin is sourcing current.
- The Fail-Safe Clock Monitor does not operate, since the system clock source is disabled.
- The LPRC clock continues to run in Sleep mode if the WDT is enabled.
- The WDT, if enabled, is automatically cleared prior to entering Sleep mode.
- Some device features or peripherals can continue to operate. This includes items such as the Input Change Notification on the I/O ports or peripherals that use an external clock input.
- Any peripheral that requires the system clock source for its operation is disabled.

The device wakes up from Sleep mode on any of the following events:

- Any interrupt source that is individually enabled
- Any form of device Reset
- A WDT time-out

On wake-up from Sleep mode, the processor restarts with the same clock source that was active when Sleep mode was entered.

For optimal power savings, the internal regulator and the Flash regulator can be configured to go into standby when Sleep mode is entered by clearing the VREGS (RCON<8>) and VREGSF (RCON<11>) bits (default configuration).

If the application requires a faster wake-up time, and can accept higher current requirements, the VREGS (RCON<8>) and VREGSF (RCON<11>) bits can be set to keep the internal regulator and the Flash regulator active during Sleep mode.

10.2.2 IDLE MODE
The following occurs in Idle mode:

- The CPU stops executing instructions.
- The WDT is automatically cleared.
- The system clock source remains active. By default, all peripheral modules continue to operate normally from the system clock source, but can also be selectively disabled (see Section 10.4 “Peripheral Module Disable”).
- If the WDT or FSCM is enabled, the LPRC also remains active.

The device wakes from Idle mode on any of the following events:

- Any interrupt that is individually enabled
- Any device Reset
- A WDT time-out

On wake-up from Idle mode, the clock is reapplied to the CPU and instruction execution will begin (2-4 clock cycles later), starting with the instruction following the PWRSAV instruction or the first instruction in the ISR.

All peripherals also have the option to discontinue operation when Idle mode is entered to allow for increased power savings. This option is selectable in the control register of each peripheral (for example, the TSIDL bit in the Timer1 Control register (T1CON<13>).

10.2.3 INTERRUPTS COINCIDENT WITH POWER SAVE INSTRUCTIONS
Any interrupt that coincides with the execution of a PWRSAV instruction is held off until entry into Sleep or Idle mode has completed. The device then wakes up from Sleep or Idle mode.
10.3 Doze Mode

The preferred strategies for reducing power consumption are changing clock speed and invoking one of the power-saving modes. In some circumstances, this cannot be practical. For example, it may be necessary for an application to maintain uninterrupted synchronous communication, even while it is doing nothing else. Reducing system clock speed can introduce communication errors, while using a power-saving mode can stop communications completely.

Doze mode is a simple and effective alternative method to reduce power consumption while the device is still executing code. In this mode, the system clock continues to operate from the same source and at the same speed. Peripheral modules continue to be clocked at the same speed, while the CPU clock speed is reduced. Synchronization between the two clock domains is maintained, allowing the peripherals to access the SFRs while the CPU executes code at a slower rate.

Doze mode is enabled by setting the DOZEN bit (CLKDIV<11>). The ratio between peripheral and core clock speed is determined by the DOZE<2:0> bits (CLKDIV<14:12>). There are eight possible configurations, from 1:1 to 1:128, with 1:1 being the default setting.

Programs can use Doze mode to selectively reduce power consumption in event-driven applications. This allows clock-sensitive functions, such as synchronous communications, to continue without interruption while the CPU Idles, waiting for something to invoke an interrupt routine. An automatic return to full-speed CPU operation on interrupts can be enabled by setting the ROI bit (CLKDIV<15>). By default, interrupt events have no effect on Doze mode operation.

10.4 Peripheral Module Disable

The Peripheral Module Disable (PMD) registers provide a method to disable a peripheral module by stopping all clock sources supplied to that module. When a peripheral is disabled using the appropriate PMD control bit, the peripheral is in a minimum power consumption state. The control and status registers associated with the peripheral are also disabled, so writes to those registers do not have any effect and read values are invalid.

A peripheral module is enabled only if both the associated bit in the PMD register is cleared and the peripheral is supported by the specific dsPIC® DSC variant. If the peripheral is present in the device, it is enabled in the PMD register by default.

Note: If a PMD bit is set, the corresponding module is disabled after a delay of one instruction cycle. Similarly, if a PMD bit is cleared, the corresponding module is enabled after a delay of one instruction cycle (assuming the module control registers are already configured to enable module operation).

10.5 Power-Saving Resources

Many useful resources are provided on the main product page of the Microchip web site for the devices listed in this data sheet. This product page contains the latest updates and additional information.

10.5.1 KEY RESOURCES

• “Watchdog Timer and Power-Saving Modes” (DS70615) in the “dsPIC33/PIC24 Family Reference Manual”
• Code Samples
• Application Notes
• Software Libraries
• Webinars
• All related “dsPIC33/PIC24 Family Reference Manual” Sections
• Development Tools

11.0 I/O PORTS

Many of the device pins are shared among the peripherals and the Parallel I/O ports. All I/O input ports feature Schmitt Trigger inputs for improved noise immunity.

11.1 Parallel I/O (PIO) Ports

Generally, a Parallel I/O port that shares a pin with a peripheral is subservient to the peripheral. The peripheral’s output buffer data and control signals are provided to a pair of multiplexers. The multiplexers select whether the peripheral or the associated port has ownership of the output data and control signals of the I/O pin. The logic also prevents “loop through”, in which a port’s digital output can drive the input of a peripheral that shares the same pin. Figure 11-1 illustrates how ports are shared with other peripherals and the associated I/O pin to which they are connected.

When a peripheral is enabled and the peripheral is actively driving an associated pin, the use of the pin as a general purpose output pin is disabled. The I/O pin can be read, but the output driver for the parallel port bit is disabled. If a peripheral is enabled, but the peripheral is not actively driving a pin, that pin can be driven by a port.

All port pins have eight registers directly associated with their operation as digital I/Os. The Data Direction register (TRISx) determines whether the pin is an input or an output. If the data direction bit is a ‘1’, then the pin is an input. All port pins are defined as inputs after a Reset. Reads from the latch (LATx), read the latch. Writes to the latch, write the latch. Reads from the port (PORTx), read the port pins, while writes to the port pins, write the latch.

Any bit and its associated data and control registers that are not valid for a particular device are disabled. This means the corresponding LATx and TRISx registers, and the port pin are read as zeros. Table 11-1 through Table 11-5 show ANSELx bits’ availability for device variants.

When a pin is shared with another peripheral or function that is defined as an input only, it is nevertheless regarded as a dedicated port because there is no other competing source of outputs.

**Legend:** — = unimplemented, read as '0'.

**Note 1:** Refer to Table 11-5 for bit availability on each pin count variant.
11.2.1 OPEN-DRAIN CONFIGURATION

In addition to the PORTx, LATx and TRISx registers for data control, port pins can also be individually configured for either digital or open-drain output. This is controlled by the Open-Drain Control x register, ODCx, associated with each port. Setting any of the bits configures the corresponding pin to act as an open-drain output.

The open-drain feature allows the generation of outputs other than VDD by using external pull-up resistors. The maximum open-drain voltage allowed on any pin is the same as the maximum VIH specification for that particular pin. See the “Pin Diagrams” section for the available 5V tolerant pins and Table 30-11 for the maximum VIH specification for each pin.

11.3 Configuring Analog and Digital Port Pins

The ANSELx register controls the operation of the analog port pins. The port pins that are to function as analog inputs or outputs must have their corresponding ANSELx and TRISx bits set. In order to use port pins for I/O functionality with digital modules, such as timers, UARTs, etc., the corresponding ANSELx bit must be cleared.

The ANSELx register has a default value of 0xFFFF; therefore, all pins that share analog functions are analog (not digital) by default.

Pins with analog functions affected by the ANSELx registers are listed with a buffer type of analog in the Pinout I/O Descriptions (see Table 1-1). Table 11-1 through Table 11-5 show ANSELx bits’ availability for device variants.

If the TRISx bit is cleared (output) while the ANSELx bit is set, the digital output level (VOH or VOL) is converted by an analog peripheral, such as the ADC module or comparator module.

When the PORTx register is read, all pins configured as analog input channels are read as cleared (a low level).

Pins configured as digital inputs do not convert an analog input. Analog levels on any pin, defined as a digital input (including the ANx pins), can cause the input buffer to consume current that exceeds the device specifications.

11.3.1 I/O PORT WRITE/READ TIMING

One instruction cycle is required between a port direction change or port write operation and a read operation of the same port. Typically, this instruction would be a NOP, as shown in Example 11-1.

11.4 Input Change Notification (ICN)

The Input Change Notification function of the I/O ports allows devices to generate interrupt requests to the processor in response to a Change-of-State (COS) on selected input pins. This feature can detect input Change-of-States, even in Sleep mode, when the clocks are disabled. Every I/O port pin can be selected (enabled) for generating an interrupt request on a Change-of-State.

Three control registers are associated with the ICN functionality of each I/O port. The CNENx registers contain the ICN interrupt enable control bits for each of the input pins. Setting any of these bits enables an ICN interrupt for the corresponding pins.

Each I/O pin also has a weak pull-up and a weak pull-down connected to it. The pull-ups and pull-downs act as a current source, or sink source, connected to the pin, and eliminate the need for external resistors when push button or keypad devices are connected. The pull-ups and pull-downs are enabled separately, using the CNPUx and the CNPDx registers, which contain the control bits for each of the pins. Setting any of the control bits enables the weak pull-ups and/or pull-downs for the corresponding pins.

Note: Pull-ups and pull-downs on Input Change Notification pins should always be disabled when the port pin is configured as a digital output.

EXAMPLE 11-1: PORT WRITE/READ EXAMPLE

```
MOV 0xFF00, W0 ; Configure PORTB<15:8> as inputs
MOV W0, TRISB ; and PORTB<7:0> as outputs
NOP ; Delay 1 cycle
BTSS PORTB, #13 ; Next Instruction
```

**Note 1:** See Table 11-1, Table 11-2, Table 11-3, Table 11-4 and Table 11-5 for individual bit availability in this register.
11.6 Peripheral Pin Select (PPS)

A major challenge in general purpose devices is providing the largest possible set of peripheral features, while minimizing the conflict of features on I/O pins. The challenge is even greater on low pin count devices. In an application where more than one peripheral needs to be assigned to a single pin, inconvenient workarounds in application code, or a complete redesign, may be the only option.

Peripheral Pin Select configuration provides an alternative to these choices by enabling peripheral set selection and placement on a wide range of I/O pins. By increasing the pinout options available on a particular device, users can better tailor the device to their entire application, rather than trimming the application to fit the device.

The Peripheral Pin Select configuration feature operates over a fixed subset of digital I/O pins. Users may independently map the input and/or output of most digital peripherals to any one of these I/O pins. Hardware safeguards are included that prevent accidental or spurious changes to the peripheral mapping once it has been established.

11.6.1 AVAILABLE PINS

The number of available pins is dependent on the particular device and its pin count. Pins that support the Peripheral Pin Select feature include the label, “RPn”, in their full pin designation, where “n” is the remappable pin number. “RP” is used to designate pins that support both remappable input and output functions.

11.6.2 AVAILABLE PERIPHERALS

The peripherals managed by the Peripheral Pin Select are all digital only peripherals. These include general serial communications (UART and SPI), general purpose timer clock inputs, timer-related peripherals (input capture and output compare) and interrupt-on-change inputs.

In comparison, some digital only peripheral modules are never included in the Peripheral Pin Select feature. This is because the peripheral’s function requires special I/O circuitry on a specific port and cannot be easily connected to multiple pins. One example includes I²C modules. A similar requirement excludes all modules with analog inputs, such as the ADC Converter.

A key difference between remappable and non-remappable peripherals is that remappable peripherals are not associated with a default I/O pin. The peripheral must always be assigned to a specific I/O pin before it can be used. In contrast, non-remappable peripherals are always available on a default pin, assuming that the peripheral is active and not conflicting with another peripheral.

When a remappable peripheral is active on a given I/O pin, it takes priority over all other digital I/Os and digital communication peripherals associated with the pin. Priority is given regardless of the type of peripheral that is mapped. Remappable peripherals never take priority over any analog functions associated with the pin.

11.6.3 CONTROLLING PERIPHERAL PIN SELECT

Peripheral Pin Select features are controlled through two sets of SFRs: one to map peripheral inputs and one to map outputs. Because they are separately controlled, a particular peripheral’s input and output (if the peripheral has both) can be placed on any selectable function pin without constraint.

The association of a peripheral to a peripheral-selectable pin is handled in two different ways, depending on whether an input or output is being mapped.
11.6.4 INPUT MAPPING

The inputs of the Peripheral Pin Select options are mapped on the basis of the peripheral. That is, a control register associated with a peripheral dictates the pin it will be mapped to. The RPINRx registers are used to configure peripheral input mapping (see Register 11-9 through Register 11-32). Each register contains sets of 8-bit fields, with each set associated with one of the remappable peripherals. Programming a given peripheral’s bit field with an appropriate 8-bit index value maps the RPn pin with the corresponding value, or internal signal, to that peripheral. See Table 11-11 for a list of available inputs.

For example, Figure 11-2 illustrates remappable pin selection for the U1RX input.

FIGURE 11-2: REMAPPABLE INPUT FOR U1RX

Note: For input only, Peripheral Pin Select functionality does not have priority over TRISx settings. Therefore, when configuring an RPn pin for input, the corresponding bit in the TRISx register must also be configured for input (set to ‘1’).

11.6.4.1 Virtual Connections

The dsPIC33EPXXXGS70X/80X devices support six virtual RPn pins (RP176-RP181), which are identical in functionality to all other RPn pins, with the exception of pinouts. These six pins are internal to the devices and are not connected to a physical device pin.

These pins provide a simple way for inter-peripheral connection without utilizing a physical pin. For example, the output of the analog comparator can be connected to RP176 and the PWM Fault input can be configured for RP176 as well. This configuration allows the analog comparator to trigger PWM Faults without the use of an actual physical pin on the device.

11.6.5 OUTPUT MAPPING

In contrast to inputs, the outputs of the Peripheral Pin Select options are mapped on the basis of the pin. In this case, a control register associated with a particular pin dictates the peripheral output to be mapped. The RPORx registers are used to control output mapping. Each register contains sets of 6-bit fields, with each set associated with one RPn pin (see Register 11-33 through Register 11-56). The value of the bit field corresponds to one of the peripherals and that peripheral’s output is mapped to the pin (see Table 11-13 and Figure 11-3).

A null output is associated with the output register Reset value of ‘0’. This is done to ensure that remappable outputs remain disconnected from all output pins by default.

FIGURE 11-3: MULTIPLEXING REMAPPABLE OUTPUTS FOR RPn

11.6.5.1 Mapping Limitations

The control schema of the peripheral select pins is not limited to a small range of fixed peripheral configurations. There are no mutual or hardware-enforced lockouts between any of the peripheral mapping SFRs. Literally any combination of peripheral mappings, across any or all of the RPn pins, is possible. This includes both many-to-one and one-to-many mappings of peripheral inputs, and outputs to pins. While such mappings may be technically possible from a configuration point of view, they may not be supportable from an electrical point of view.

**Note 1:** PPS outputs are only available on dsPIC33EPXXXGS702 (28-pin) devices.
11.7 I/O Helpful Tips

1. In some cases, certain pins, as defined in Table 30-11 under “Injection Current”, have internal protection diodes to VDD and VSS. The term, “Injection Current”, is also referred to as “Clamp Current”. On designated pins, with sufficient external current-limiting precautions by the user, I/O pin input voltages are allowed to be greater or less than the data sheet absolute maximum ratings, with respect to the VSS and VDD supplies. Note that when the user application forward biases either of the high or low-side internal input clamp diodes, that the resulting current being injected into the device, that is clamped internally by the VDD and VSS power rails, may affect the ADC accuracy by four to six counts.

2. I/O pins that are shared with any analog input pin (i.e., ANx) are always analog pins, by default, after any Reset. Consequently, configuring a pin as an analog input pin automatically disables the digital input pin buffer and any attempt to read the digital input level by reading PORTx or LATx will always return a ‘0’, regardless of the digital logic level on the pin. To use a pin as a digital I/O pin on a shared ANx pin, the user application needs to configure the Analog Pin Configuration registers (i.e., ANSELx) in the I/O ports module by setting the appropriate bit that corresponds to that I/O port pin to a ‘0’.

Note: Although it is not possible to use a digital input pin when its analog function is enabled, it is possible to use the digital I/O output function, TRISx = 0x0, while the analog function is also enabled. However, this is not recommended, particularly if the analog input is connected to an external analog voltage source, which would create signal contention between the analog signal and the output pin driver.

3. Most I/O pins have multiple functions. Referring to the device pin diagrams in this data sheet, the priorities of the functions allocated to any pins are indicated by reading the pin name from left-to-right. The left most function name takes precedence over any function to its right in the naming convention. For example: AN16/T2CK/T7CK/RC1; this indicates that AN16 is the highest priority in this example and will supersede all other functions to its right in the list. Those other functions to its right, even if enabled, would not work as long as any other function to its left was enabled. This rule applies to all of the functions listed for a given pin.

4. Each pin has an internal weak pull-up resistor and pull-down resistor that can be configured using the CNPUx and CNPDx registers, respectively. These resistors eliminate the need for external resistors in certain applications. The internal pull-up is up to ~(VDD – 0.8), not VDD. This value is still above the minimum VIH of CMOS and TTL devices.

5. When driving LEDs directly, the I/O pin can source or sink more current than what is specified in the VOH/IOH and VOL/IOL DC characteristics specification. The respective IOH and IOL current rating only applies to maintaining the corresponding output at or above the VOH, and at or below the VOL levels. However, for LEDs, unlike digital inputs of an externally connected device, they are not governed by the same minimum VIH/VIL levels. An I/O pin output can safely sink or source any current less than that listed in the Absolute Maximum Ratings in Section 30.0 “Electrical Characteristics” of this data sheet. For example:

\[
\text{VOH} = 2.4V \quad \text{at } \text{IOH} = -8 \text{ mA} \quad \text{and } \text{VDD} = 3.3V
\]

The maximum output current sourced by any 8 mA I/O pin = 12 mA.

LED source current < 12 mA is technically permitted. Refer to the VOH/IOH graphs in Section 31.0 “DC and AC Device Characteristics Graphs” for additional information.
6. The Peripheral Pin Select (PPS) pin mapping rules are as follows:
   a) Only one "output" function can be active on a given pin at any time, regardless if it is a dedicated or remappable function (one pin, one output).
   b) It is possible to assign a "remappable output" function to multiple pins and externally short or tie them together for increased current drive.
   c) If any "dedicated output" function is enabled on a pin, it will take precedence over any remappable "output" function.
   d) If any "dedicated digital" (input or output) function is enabled on a pin, any number of "input" remappable functions can be mapped to the same pin.
   e) If any "dedicated analog" function(s) are enabled on a given pin, "digital input(s)" of any kind will all be disabled, although a single "digital output", at the user's cautionary discretion, can be enabled and active as long as there is no signal contention with an external analog input signal. For example, it is possible for the ADC to convert the digital output logic level, or to toggle a digital output on a comparator or ADC input, provided there is no external analog input, such as for a built-in self-test.
   f) Any number of "input" remappable functions can be mapped to the same pin(s) at the same time, including to any pin with a single output from either a dedicated or remappable "output".
   g) The TRISx registers control only the digital I/O output buffer. Any other dedicated or remappable active "output" will automatically override the TRISx setting. The TRISx register does not control the digital logic "input" buffer. Remappable digital "inputs" do not automatically override TRISx settings, which means that the TRISx bit must be set to input for pins with only remappable input function(s) assigned.
   h) All analog pins are enabled by default after any Reset and the corresponding digital input buffer on the pin has been disabled. Only the Analog Pin Select x (ANSELx) registers control the digital input buffer, not the TRISx register. The user must disable the analog function on a pin using the Analog Pin Select x registers in order to use any "digital input(s)" on a corresponding pin, no exceptions.

11.8 I/O Ports Resources

Many useful resources are provided on the main product page of the Microchip web site for the devices listed in this data sheet. This product page contains the latest updates and additional information.

11.8.1 KEY RESOURCES

• "I/O Ports" (DS70000598) in the "dsPIC33/PIC24 Family Reference Manual"
• Code Samples
• Application Notes
• Software Libraries
• Webinars
• All Related "dsPIC33/PIC24 Family Reference Manual" Sections

12.0 TIMER1

The Timer1 module is a 16-bit timer that can operate as a free-running interval timer/counter.

The Timer1 module has the following unique features over other timers:

- Can be Operated in Asynchronous Counter mode from an External Clock Source
- The External Clock Input (T1CK) can Optionally be Synchronized to the Internal Device Clock and the Clock Synchronization is Performed after the prescaler

A block diagram of Timer1 is shown in Figure 12-1.

The Timer1 module can operate in one of the following modes:

- Timer mode
- Gated Timer mode
- Synchronous Counter mode
- Asynchronous Counter mode

In Timer and Gated Timer modes, the input clock is derived from the internal instruction cycle clock (FCy). In Synchronous and Asynchronous Counter modes, the input clock is derived from the external clock input at the T1CK pin.

The Timer modes are determined by the following bits:

- Timer1 Clock Source Select bit (TCS): T1CON<1>
- Timer1 External Clock Input Synchronization Select bit (TSYNC): T1CON<2>
- Timer1 Gated Time Accumulation Enable bit (TGATE): T1CON<6>

Timer control bit settings for different operating modes are provided in Table 12-1.

- 1 = Starts 16-bit Timer1
- 0 = Stops 16-bit Timer1

bit 14 **Unimplemented**: Read as '0'

bit 13 **TSIDL**: Timer1 Stop in Idle Mode bit

- 1 = Discontinues module operation when device enters Idle mode
- 0 = Continues module operation in Idle mode

bit 12-7 **Unimplemented**: Read as '0'

bit 6 **TGATE**: Timer1 Gated Time Accumulation Enable bit

- When TCS = 1:
  - This bit is ignored.
- When TCS = 0:
  - 1 = Gated time accumulation is enabled
  - 0 = Gated time accumulation is disabled

bit 5-4 **TCKPS<1:0>**: Timer1 Input Clock Prescale Select bits

- 11 = 1:256
- 10 = 1:64
- 01 = 1:8
- 00 = 1:1

bit 3 **Unimplemented**: Read as '0'

bit 2 **TSYNC**: Timer1 External Clock Input Synchronization Select bit<1>

- When TCS = 1:
  - 1 = Synchronizes external clock input
  - 0 = Does not synchronize external clock input
- When TCS = 0:
  - This bit is ignored.

bit 1 **TCS**: Timer1 Clock Source Select bit<1>

- 1 = External clock is from pin, T1CK (on the rising edge)
- 0 = Internal clock (FP)

bit 0 **Unimplemented**: Read as '0'

**Note 1**: When Timer1 is enabled in External Synchronous Counter mode (TCS = 1, TSYNC = 1, TON = 1), any attempts by user software to write to the TMR1 register are ignored.
13.0 TIMERS 2/3 AND TIMERS 4/5

Note 1: This data sheet summarizes the features of the dsPIC33EPXXXGS70X/80X family of devices. It is not intended to be a comprehensive reference source. To complement the information in this data sheet, refer to “Timers” (DS70362) in the “dsPIC33/PIC24 Family Reference Manual”, which is available from the Microchip web site (www.microchip.com).

Note 2: Some registers and associated bits described in this section may not be available on all devices. Refer to Section 4.0 “Memory Organization” in this data sheet for device-specific register and bit information.

The Timer2/3 and Timer4/5 modules are 32-bit timers, which can also be configured as four independent 16-bit timers with selectable operating modes.

As 32-bit timers, Timer2/3 and Timer4/5 operate in three modes:

• Two Independent 16-Bit Timers (e.g., Timer2 and Timer3) with all 16-Bit Operating modes (except Asynchronous Counter mode)
• Single 32-Bit Timer
• Single 32-Bit Synchronous Counter

They also support these features:

• Timer Gate Operation
• Selectable Prescaler Settings
• Timer Operation during Idle and Sleep modes
• Interrupt on a 32-Bit Period Register Match
• Time Base for Input Capture and Output Compare modules (Timer2 and Timer3 only)

Individually, all four of the 16-bit timers can function as synchronous timers or counters. They also offer the features listed previously, except for the event trigger; this is implemented only with Timer2/3. The operating modes and enabled features are determined by setting the appropriate bit(s) in the T2CON, T3CON, T4CON and T5CON registers. T2CON and T4CON are shown in generic form in Register 13-1. T3CON and T5CON are shown in Register 13-2.

For 32-bit timer/counter operation, Timer2 and Timer4 are the least significant word (lsw); Timer3 and Timer5 are the most significant word (msw) of the 32-bit timers.

Note: For 32-bit operation, T3CON and T5CON control bits are ignored. Only T2CON and T4CON control bits are used for setup and control. Timer2 and Timer4 clock and gate inputs are utilized for the 32-bit timer modules, but an interrupt is generated with the Timer3 and Timer5 interrupt flags.

A block diagram for an example 32-bit timer pair (Timer2/3 and Timer4/5) is shown in Figure 13-2.

13.1 Timer Resources

Many useful resources are provided on the main product page of the Microchip web site for the devices listed in this data sheet. This product page contains the latest updates and additional information.

13.1.1 KEY RESOURCES

• “Timers” (DS70362) in the “dsPIC33/PIC24 Family Reference Manual”
• Code Samples
• Application Notes
• Software Libraries
• Webinars
• All Related “dsPIC33/PIC24 Family Reference Manual” Sections
• Development Tools
FIGURE 13-1: TIMERx BLOCK DIAGRAM (x = 2 THROUGH 5)

- **Gate Sync**: Syncs the input signals.
- **Prescaler (n)**: Divides the input clock by n.
- **Falling Edge Detect**: Detects falling edges of the input signal.
- **PRx**: Prescaler output.
- **Comparator**: Compares the input with the prescaler output.
- **TMRx**: Timer register.
- **Set TxIF Flag**: Sets the timer interrupt flag.
- **ADC Trigger**: Used to trigger the ADC.

**Notes:**
1. FP is the peripheral clock.
2. The ADC trigger is only available on TMR2.

---

FIGURE 13-2: TYPE B/TYPE C TIMER PAIR BLOCK DIAGRAM (32-BIT TIMER)

- **Gate Sync**: Syncs the input signals.
- **Prescaler (n)**: Divides the input clock by n.
- **Falling Edge Detect**: Detects falling edges of the input signal.
- **PRx**: Prescaler output.
- **Comparator**: Compares the input with the prescaler output.
- **PRy**: Prescaler output.
- **TMRx**: Timer register.
- **TMRy**: Timer register.
- **Latch**: Latches the output data.
- **Set TylF Flag**: Sets the timer interrupt flag.
- **Data Bus<15:0>**: Data bus for output.

**Notes:**
1. Timerx is a Type B timer (x = 2 and 4).
2. Timery is a Type C timer (y = 3 and 5).

- **TCS**: Timery Clock Source Select bit\(^{(1,3)}\)
  - 1 = External clock is from pin, TyCK (on the rising edge)
  - 0 = Internal clock (FP)

**bit 0**

- **Unimplemented**: Read as ‘0’

**Note 1**: When 32-bit operation is enabled (TxCON<3> = 1), these bits have no effect on Timery operation; all timer functions are set through TxCON.

**Note 2**: When 32-bit timer operation is enabled (T32 = 1) in the Timerx Control register (TxCON<3>), the TSIDL bit must be cleared to operate the 32-bit timer in Idle mode.

**Note 3**: The TyCK pin is not available on all devices. See the “Pin Diagrams” section for the available pins.
14.0 INPUT CAPTURE

The input capture module is useful in applications requiring frequency (period) and pulse measurements. The dsPIC33EPXXXGS70X/80X devices support four input capture channels.

Key features of the input capture module include:
- Hardware-Configurable for 32-Bit Operation in all modes by Cascading Two Adjacent modules
- Synchronous and Trigger modes of Output Compare Operation, with up to 21 User-Selectable Trigger/Sync Sources available
- A 4-Level FIFO Buffer for Capturing and Holding Timer Values for Several Events
- Configurable Interrupt Generation
- Up to Six Clock Sources available for each module, Driving a Separate Internal 16-Bit Counter

14.1 Input Capture Resources

Many useful resources are provided on the main product page of the Microchip web site for the devices listed in this data sheet. This product page contains the latest updates and additional information.

**Note**

1: The IC32 bit in both the odd and even ICx must be set to enable Cascade mode.
2: The input source is selected by the SYNCSSEL<4:0> bits of the ICxCON2 register.
3: This bit is set by the selected input source (selected by SYNCSSEL<4:0> bits); it can be read, set and cleared in software.
4: Do not use the ICx module as its own sync or trigger source.
5: This option should only be selected as a trigger source and not as a synchronization source.
15.0 OUTPUT COMPARE

The output compare module can select one of six available clock sources for its time base. The module compares the value of the timer with the value of one or two Compare registers, depending on the operating mode selected. The state of the output pin changes when the timer value matches the Compare register value. The output compare module generates either a single output pulse, or a sequence of output pulses, by changing the state of the output pin on the compare match events. The output compare module can also generate interrupts on compare match events.

15.1 Output Compare Resources

Many useful resources are provided on the main product page of the Microchip web site for the devices listed in this data sheet. This product page contains the latest updates and additional information.

## 15.2 Output Compare Control Registers

### REGISTER 15-1: OCxCON1: OUTPUT COMPARE x CONTROL REGISTER 1

| bit 15-14 | Unimplemented: Read as '0' |
| bit 13    | OCSIDL: Output Compare x Stop in Idle Mode Control bit |
|          | 1 = Output Compare x halts in CPU Idle mode |
|          | 0 = Output Compare x continues to operate in CPU Idle mode |
| bit 12-10 | OCTSEL<2:0>: Output Compare x Clock Select bits |
|          | 111 = Peripheral clock (FP) |
|          | 110 = Reserved |
|          | 101 = Reserved |
|          | 100 = T1CLK is the clock source of the OCx (only the synchronous clock is supported) |
|          | 011 = T5CLK is the clock source of the OCx |
|          | 010 = T4CLK is the clock source of the OCx |
|          | 001 = T3CLK is the clock source of the OCx |
|          | 000 = T2CLK is the clock source of the OCx |
| bit 9-8  | Unimplemented: Read as '0' |
| bit 7    | ENFLTA: Fault A Input Enable bit |
|          | 1 = Output Compare Fault A input (OCFA) is enabled |
|          | 0 = Output Compare Fault A input (OCFA) is disabled |
| bit 6-5  | Unimplemented: Read as '0' |
| bit 4    | OCFLTA: PWM Fault A Condition Status bit |
|          | 1 = PWM Fault A condition on the OCFA pin has occurred |
|          | 0 = No PWM Fault A condition on the OCFA pin has occurred |
| bit 3    | TRIGMODE: Trigger Status Mode Select bit |
|          | 1 = TRIGSTAT (OCxCON2<6>) is cleared when OCxRS = OCxTMR or in software |
|          | 0 = TRIGSTAT is cleared only by software |

**Note:** OCxR and OCxRS are double-buffered in PWM mode only.
bit 2-0  OCM<2:0>: Output Compare x Mode Select bits

111 = Center-Aligned PWM mode: Output is set high when OCxTMR = OCxR and set low when OCxTMR = OCxRS(1)
110 = Edge-Aligned PWM mode: Output is set high when OCxTMR = 0 and set low when OCxTMR = OCxR(1)
101 = Double Compare Continuous Pulse mode: Initializes OCx pin low, toggles OCx state continuously on alternate matches of OCxR and OCxRS
100 = Double Compare Single-Shot mode: Initializes OCx pin low, toggles OCx state on matches of OCxR and OCxRS for one cycle
011 = Single Compare mode: Compare event with OCxR, continuously toggles OCx pin
010 = Single Compare Single-Shot mode: Initializes OCx pin high, compare event with OCxR, forces OCx pin low
001 = Single Compare Single-Shot mode: Initializes OCx pin low, compare event with OCxR, forces OCx pin high
000 = Output compare channel is disabled

Note 1: OCxR and OCxRS are double-buffered in PWM mode only.

- U = Unimplemented bit, read as ‘0’
- ‘1’ = Bit is set
- ‘0’ = Bit is cleared
- x = Bit is unknown

bit 15  FLTMD: Fault Mode Select bit

1 = Fault mode is maintained until the Fault source is removed; the corresponding OCFLTA bit is cleared in software and a new PWMx period starts
0 = Fault mode is maintained until the Fault source is removed and a new PWMx period starts

bit 14  FLTOUT: Fault Out bit

1 = PWMx output is driven high on a Fault
0 = PWMx output is driven low on a Fault

bit 13  FLTTRIEN: Fault Output State Select bit

1 = OCx pin is tri-stated on a Fault condition
0 = OCx pin I/O state is defined by the FLTOUT bit on a Fault condition

bit 12  OCINV: Output Compare x Invert bit

1 = OCx output is inverted
0 = OCx output is not inverted

bit 11-9  Unimplemented: Read as ‘0’

bit 8  OC32: Cascade Two OCx Modules Enable bit (32-bit operation)

1 = Cascade module operation is enabled
0 = Cascade module operation is disabled

bit 7  OCTRIG: Output Compare x Trigger/Sync Select bit

1 = Triggers OCx from the source designated by the SYNCSELx bits
0 = Synchronizes OCx with the source designated by the SYNCSELx bits

bit 6  TRIGSTAT: Timer Trigger Status bit

1 = Timer source has been triggered and is running
0 = Timer source has not been triggered and is being held clear

bit 5  OCTRIS: Output Compare x Output Pin Direction Select bit

1 = OCx is tri-stated
0 = OCx module drives the OCx pin

Note 1: Do not use the OCx module as its own synchronization or trigger source.

2: When the OCy module is turned off, it sends a trigger out signal. If the OCx module uses the OCy module as a trigger source, the OCy module must be unselected as a trigger source prior to disabling it.

3: For each OCMPx instance, a different PTG trigger out is used:

- OCMP1 – PTG trigger out [0]
- OCMP2 – PTG trigger out [1]
- OCMP3 – PTG trigger out [2]

dsPIC33EPXXXGS70X/80X FAMILY

16.0 HIGH-SPEED PWM

The high-speed PWM on dsPIC33EPXXXGS70X/80X devices supports a wide variety of PWM modes and output formats. This PWM module is ideal for power conversion applications, such as:

- AC/DC Converters
- DC/DC Converters
- Power Factor Correction
- Uninterruptible Power Supply (UPS)
- Inverters
- Battery Chargers
- Digital Lighting

16.1 Features Overview

The high-speed PWM module incorporates the following features:

- Eight PWMx Generators with Two Outputs per Generator
- Two Master Time Base modules
- Individual Time Base and Duty Cycle for each PWM Output
- Duty Cycle, Dead Time, Phase Shift and a Frequency Resolution of 1.04 ns
- Independent Fault and Current-Limit Inputs
- Redundant Output
- True Independent Output
- Center-Aligned PWM mode
- Output override control
- Chop mode (also known as Gated mode)
- Special Event Trigger
- Dual Trigger from PWMx to Analog-to-Digital Converter (ADC)
- PWMxL and PWMxH Output Pin Swapping
- Independent PWMx Frequency, Duty Cycle and Phase-Shift Changes
- Enhanced Leading-Edge Blanking (LEB) Functionality
- PWM Capture Functionality

Note: Duty cycle, dead time, phase shift and frequency resolution is 8.32 ns in Center-Aligned PWM mode.

Figure 16-1 conceptualizes the PWM module in a simplified block diagram. Figure 16-2 illustrates how the module hardware is partitioned for each PWMx output pair for the Complementary PWM mode.

The PWM module contains eight PWM generators. The module has up to 16 PWMx output pins: PWM1H/PWM1L through PWM8H/PWM8L. For complementary outputs, these 16 I/O pins are grouped into high/low pairs. PWM1 through PWM6 can be used to trigger an ADC conversion.

16.2 Feature Description

The PWM module is designed for applications that require:

- High resolution at high PWM frequencies
- The ability to drive Standard, Edge-Aligned, Center-Aligned Complementary mode and Push-Pull mode outputs
- The ability to create multiphase PWM outputs

Two common, medium power converter topologies are push-pull and half-bridge. These designs require the PWM output signal to be switched between alternate pins, as provided by the Push-Pull PWM mode.

Phase-shifted PWM describes the situation where each PWM generator provides outputs, but the phase relationship between the generator outputs is specifiable and changeable.

Multiphase PWM is often used to improve DC/DC Converter load transient response, and reduce the size of output filter capacitors and inductors. Multiple DC/DC Converters are often operated in parallel, but phase shifted in time. A single PWM output, operating at 250 kHz, has a period of 4 μs but an array of four PWM channels, staggered by 1 μs each, yields an effective switching frequency of 1 MHz. Multiphase PWM applications typically use a fixed-phase relationship.

Variable phase PWM is useful in Zero Voltage Transition (ZVT) power converters. Here, the PWM duty cycle is always 50% and the power flow is controlled by varying the relative phase shift between the two PWM generators.
16.2.1 WRITE-PROTECTED REGISTERS

On dsPIC33EPXXXGS70X/80X family devices, write protection is implemented for the IOCONx and FCLCONx registers. The write protection feature prevents any inadvertent writes to these registers. This protection feature can be controlled by the PWMLOCK Configuration bit (FDEVOPT<0>). The default state of the write protection feature is enabled (PWMLOCK = 1). The write protection feature can be disabled by configuring PWMLOCK = 0.

To gain write access to these locked registers, the user application must write two consecutive values (0xABCD and 0x4321) to the PWMKEY register to perform the unlock operation. The write access to the IOCONx or FCLCONx registers must be the next SFR access following the unlock process. There can be no other SFR accesses during the unlock process and subsequent write access. To write to both the IOCONx and FCLCONx registers requires two unlock operations. The correct unlocking sequence is described in Example 16-1.

EXAMPLE 16-1: PWM WRITE-PROTECTED REGISTER UNLOCK SEQUENCE

```
; Writing to FCLCON1 register requires unlock sequence
mov #0xabcd, w10 ; Load first unlock key to w10 register
mov #0x4321, w11 ; Load second unlock key to w11 register
mov w10, PWMKEY ; Write first unlock key to PWMKEY register
mov w11, PWMKEY ; Write second unlock key to PWMKEY register
mov w0, FCLCON1 ; Write desired value to FCLCON1 register

; Set PWM ownership and polarity using the IOCON1 register
; Writing to IOCON1 register requires unlock sequence
mov #0xabcd, w10 ; Load first unlock key to w10 register
mov #0x4321, w11 ; Load second unlock key to w11 register
mov #0xF000, w0 ; Load desired value of IOCON1 register in w0
mov w10, PWMKEY ; Write first unlock key to PWMKEY register
mov w11, PWMKEY ; Write second unlock key to PWMKEY register
mov w0, IOCON1 ; Write desired value to IOCON1 register
```

- x = Bit is unknown

bit 15 FLTSTAT: Fault Interrupt Status bit(1)
1 = Fault interrupt is pending
0 = No Fault interrupt is pending
This bit is cleared by setting FLTIEN = 0.

bit 14 CLSTAT: Current-Limit Interrupt Status bit(1)
1 = Current-limit interrupt is pending
0 = No current-limit interrupt is pending
This bit is cleared by setting CLIEN = 0.

bit 13 TRGSTAT: Trigger Interrupt Status bit
1 = Trigger interrupt is pending
0 = No trigger interrupt is pending
This bit is cleared by setting TRGIEN = 0.

bit 12 FLTIEN: Fault Interrupt Enable bit
1 = Fault interrupt is enabled
0 = Fault interrupt is disabled and the FLTSTAT bit is cleared

bit 11 CLIEN: Current-Limit Interrupt Enable bit
1 = Current-limit interrupt is enabled
0 = Current-limit interrupt is disabled and the CLSTAT bit is cleared

bit 10 TRGIEN: Trigger Interrupt Enable bit
1 = A trigger event generates an interrupt request
0 = Trigger event interrupts are disabled and the TRGSTAT bit is cleared

bit 9 ITB: Independent Time Base Mode bit(3)
1 = PHASEx/SPHASEx registers provide the time base period for this PWMx generator
0 = PTPER register provides timing for this PWMx generator

bit 8 MDCS: Master Duty Cycle Register Select bit(3)
1 = MDC register provides duty cycle information for this PWMx generator
0 = PDCx and SDCx registers provide duty cycle information for this PWMx generator

Note 1: Software must clear the interrupt status here and in the corresponding IFSx bit in the interrupt controller.

2: The Independent Time Base mode (ITB = 1) must be enabled to use Center-Aligned mode. If ITB = 0, the CAM bit is ignored.

3: These bits should not be changed after the PWMx is enabled by setting PTEN (PTCON<15>) = 1.

4: Center-Aligned mode ignores the Least Significant 3 bits of the Duty Cycle, Phase and Dead-Time registers. The highest Center-Aligned mode resolution available is 8.32 ns with the clock prescaler set to the fastest clock.

5: Configure CLMOD (FCLCONx<8>) = 0 and ITB (PWMCONx<9>) = 1 to operate in External Period Reset mode.
REGISTER 16-12: PWMCONx: PWMx CONTROL REGISTER (x = 1 to 8) (CONTINUED)

         11 = Reserved
         10 = Dead-time function is disabled
         01 = Negative dead time is actively applied for Complementary Output mode
         00 = Positive dead time is actively applied for all Output modes

bit 5-4  Unimplemented: Read as ‘0’

bit 3  MTBS: Master Time Base Select bit
         1 = PWMx generator uses the secondary master time base for synchronization and the clock source for
         the PWMx generation logic (if secondary time base is available)
         0 = PWMx generator uses the primary master time base for synchronization and the clock source for the
         PWMx generation logic

bit 2  CAM: Center-Aligned Mode Enable bit\(^{(2,3,4)}\)
         1 = Center-Aligned mode is enabled
         0 = Edge-Aligned mode is enabled

bit 1  XPRES: External PWMx Reset Control bit\(^{(5)}\)
         1 = Current-limit source resets the time base for this PWMx generator if it is in Independent Time Base mode
         0 = External pins do not affect the PWMx time base

bit 0  IUE: Immediate Update Enable bit
         1 = Updates to the active Duty Cycle, Phase Offset, Dead-Time and local Time Base Period registers are
         immediate
         0 = Updates to the active Duty Cycle, Phase Offset, Dead-Time and local Time Base Period registers are
         synchronized to the local PWMx time base

Note 1:  Software must clear the interrupt status here and in the corresponding IFSx bit in the interrupt controller.
2:  The Independent Time Base mode (ITB = 1) must be enabled to use Center-Aligned mode. If ITB = 0, the
    CAM bit is ignored.
3:  These bits should not be changed after the PWMx is enabled by setting PTEN (PTCON<15>) = 1.
4:  Center-Aligned mode ignores the Least Significant 3 bits of the Duty Cycle, Phase and Dead-Time
    registers. The highest Center-Aligned mode resolution available is 8.32 ns with the clock prescaler set to
    the fastest clock.
5:  Configure CLMOD (FCLCONx<8>) = 0 and ITB (PWMCONx<9>) = 1 to operate in External Period Reset mode.
**REGISTER 16-13: PDCx: PWMx GENERATOR DUTY CYCLE REGISTER (x = 1 to 8)**

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>15-0</td>

- **x** = Bit is unknown

bit 15-0 SPHASE<15:0>: Secondary Phase Offset for PWMxL Output Pin bits (used in Independent PWM mode only)

Note 1: If PWMCONx<9> = 0, the following applies based on the mode of operation:
- Complementary, Redundant and Push-Pull Output mode (IOCONx<11:10> = 00, 01 or 10);
  SPHASE<15:0> = Not used
- True Independent Output mode (IOCONx<11:10> = 11), PHASE<15:0> = Phase-shift value for PWMxL only

2: If PWMCONx<9> = 1, the following applies based on the mode of operation:
- Complementary, Redundant and Push-Pull Output mode (IOCONx<11:10> = 00, 01 or 10);
  SPHASE<15:0> = Not used
- True Independent Output mode (IOCONx<11:10> = 11); PHASE<15:0> = Independent time base period value for PWMxL only
- When the PHASE<SPHASE< registers provide the local period, the valid range of values is 0x0010-0xFFFF

bit 15-3  PWMCAP<12:0>: PWMx Primary Time Base Capture Value bits(1,2,3,4)
The value in this register represents the captured PWMx time base value when a leading edge is detected on the current-limit input.

bit 2-0  Unimplemented: Read as ‘0’

Note 1: The capture feature is only available on a primary output (PWMxH).
2: This feature is active only after LEB processing on the current-limit input signal is complete.
3: The minimum capture resolution is 8.32 ns.
4: This feature can be used when the XPRES bit (PWMCONx<1>) is set to ‘0’.
17.0 PERIPHERAL TRIGGER GENERATOR (PTG) MODULE

Note 1: This data sheet summarizes the features of the dsPIC33EPXXXGS70X/80X family of devices. It is not intended to be a comprehensive reference source. To complement the information in this data sheet, refer to “Peripheral Trigger Generator (PTG)” (DS70669) in the “dsPIC33/PIC24 Family Reference Manual”, which is available from the Microchip web site (www.microchip.com).

2: Some registers and associated bits described in this section may not be available on all devices. Refer to Section 4.0 “Memory Organization” in this data sheet for device-specific register and bit information.

17.1 Module Introduction

The Peripheral Trigger Generator (PTG) provides a means to schedule complex, high-speed peripheral operations that would be difficult to achieve using software. The PTG module uses 8-bit commands, called “Steps”, that the user writes to the PTG Queue register (PTGQUE0-PTQUE15) which performs operations, such as wait for input signal, generate output trigger and wait for timer.

The PTG module has the following major features:

- Multiple Clock Sources
- Two 16-Bit General Purpose Timers
- Two 16-Bit General Limit Counters
- Configurable for Rising or Falling Edge Triggering
- Generates Processor Interrupts to include:
  - Four configurable processor interrupts
  - Interrupt on a Step event in Single-Step mode
  - Interrupt on a PTG Watchdog Timer time-out
- Able to Receive Trigger Signals from these Peripherals:
  - ADC
  - PWM
  - Output Compare
  - Input Capture
  - Comparator
  - INT2
- Able to Trigger or Synchronize to these Peripherals:
  - Watchdog Timer
  - Output Compare
  - Input Capture
  - ADC
  - PWM
  - Comparator
FIGURE 17-1: PTG BLOCK DIAGRAM

Note 1: This is a dedicated Watchdog Timer for the PTG module and is independent of the device Watchdog Timer.
### 17.2 PTG Control Registers

**REGISTER 17-1: PTGCST: PTG CONTROL/STATUS REGISTER**

<table>

</tr>
</tbody>
</table>

#### Legend:
- **R** = Readable bit
- **W** = Writable bit
- **U** = Unimplemented bit, read as ‘0’
- **-n** = Value at POR
- ‘1’ = Bit is set
- ‘0’ = Bit is cleared
- **x** = Bit is unknown

#### Description:

- **bit 15 (PTGEN):** PTG Module Enable bit
  - 1 = PTG module is enabled
  - 0 = PTG module is disabled

- **bit 14 (Unimplemented):** Read as ‘0’

- **bit 13 (PTGSIDL):** PTG Stop in Idle Mode bit
  - 1 = Discontinues module operation when device enters Idle mode
  - 0 = Continues module operation in Idle mode

- **bit 12 (PTGTOGL):** PTG TRIG Output Toggle Mode bit
  - 1 = Toggles the state of the PTGOx for each execution of the PTGTRIG command
  - 0 = Each execution of the PTGTRIG command will generate a single PTGOx pulse determined by the value in the PTGPWDx bits

- **bit 11 (Unimplemented):** Read as ‘0’

- **bit 10 (PTGSWT):** PTG Software Trigger bit
  - 1 = Triggers the PTG module
  - 0 = No action (clearing this bit will have no effect)

- **bit 9 (PTGSSEN):** PTG Enable Single-Step bit
  - 1 = Enables Single-Step mode
  - 0 = Disables Single-Step mode

- **bit 8 (PTGIVIS):** PTG Counter/Timer Visibility Control bit
  - 1 = Reads of the PTGSDLIM, PTGCxLIM or PTGTxLIM registers return the current values of their corresponding Counter/Timer registers (PTGSD, PTGCx, PTGTx)
  - 0 = Reads of the PTGSDLIM, PTGCxLIM or PTGTxLIM registers return the value previously written to those PTG Limit registers

- **bit 7 (PTGSTRT):** Start PTG Sequencer bit
  - 1 = Starts to sequentially execute commands (Continuous mode)
  - 0 = Stops executing commands

- **bit 6 (PTGWDTO):** PTG Watchdog Timer Time-out Status bit
  - 1 = PTG Watchdog Timer has timed out
  - 0 = PTG Watchdog Timer has not timed out

- **bit 5-2 (Unimplemented):** Read as ‘0’

#### Notes:

1. These bits apply to the PTGWHI and PTGWLO commands only.
2. This bit is only used with the PTGCTRL Step command software trigger option.
REGISTER 17-1:  PTGCST: PTG CONTROL/STATUS REGISTER (CONTINUED)

bit 1-0  PTGITM<1:0>: PTG Input Trigger Command Operating Mode bits(f)

11 = Single level detect with Step delay is not executed on exit of command (regardless of PTGCTRL command)
10 = Single level detect with Step delay is executed on exit of command
01 = Continuous edge detect with Step delay is not executed on exit of command (regardless of PTGCTRL command)
00 = Continuous edge detect with Step delay is executed on exit of command

Note 1: These bits apply to the PTGWHI and PTGWLO commands only.
2: This bit is only used with the PTGCTRL Step command software trigger option.

- x = Bit is unknown

**bit 15-0 PTGADJ<15:0>: PTG Adjust Register bits**

This register holds user-supplied data to be added to the PTGTxLIM, PTGCxLIM, PTGSDLIM or PTGL0 register with the PTGADD command.

**Note 1:** This register is read-only when the PTG module is executing Step commands (PTGEN = 1 and PTGSTRT = 1).

18.0 SERIAL PERIPHERAL INTERFACE (SPI)

The Serial Peripheral Interface (SPI) module is a synchronous serial interface useful for communicating with other peripheral or microcontroller devices. These peripheral devices may be serial EEPROMs, shift registers, display drivers, A/D Converters, etc. The SPI module is compatible with the Motorola® SPI and SIOP interfaces. All devices in the dsPIC33EPXXXGS70X/80X family include three SPI modules.

The module supports operation in two buffer modes. In Standard mode, data is shifted through a single serial buffer. In Enhanced Buffer mode, data is shifted through a FIFO buffer. The FIFO level depends on the configured mode.

Variable length data can be transmitted and received, from 2 to 32 bits.

The SPI module also supports a basic framed SPI protocol while operating in either Master or Slave mode. A total of four framed SPI configurations are supported.

SPI3 also supports Audio modes. Four different Audio modes are available.

• I²S
• Left Justified
• Right Justified
• PCM/DSP

In each of these modes, the serial clock is free-running and audio data is always transferred.

If an audio protocol data transfer takes place between two devices, then usually one device is the master and the other is the slave. However, audio data can be transferred between two slaves. Because the audio protocols require free-running clocks, the master can be a third party controller. In either case, the master generates two free-running clocks: SCKx and LRC (Left, Right Channel Clock/SSx/FSYNC).

The SPI serial interface consists of four pins:

- SDIx: Serial Data Input
- SDOx: Serial Data Output
- SCKx: Shift Clock Input or Output
- SSx: Active-Low Slave Select or Frame Synchronization I/O Pulse

The SPI module can be configured to operate using 2, 3 or 4 pins. In the 3-pin mode, SSx is not used. In the 2-pin mode, both SDOx and SSx are not used.

The SPI module has the ability to generate three interrupts, reflecting the events that occur during the data communication. The following types of interrupts can be generated:

1. Receive interrupts are signalled by SPIxRXIF. This event occurs when:
   - RX watermark interrupt
   - SPIROV = 1
   - SPIRBF = 1
   - SPIRBE = 1
   provided the respective mask bits are enabled in SPIxIMSKL/H.

2. Transmit interrupts are signalled by SPIxTXIF. This event occurs when:
   - TX watermark interrupt
   - SPITUR = 1
   - SPITBF = 1
   - SPITBE = 1
   provided the respective mask bits are enabled in SPIxIMSKL/H.

3. General interrupts are signalled by SPIxIF. This event occurs when:
   - FRMERR = 1
   - SPIBUSY = 1
   - SRM = 1
   provided the respective mask bits are enabled in SPIxIMSKL/H.

Block diagrams of the module in Standard and Enhanced modes are shown in Figure 18-1 and Figure 18-2.
To set up the SPIx module for the Standard Master mode of operation:

1. If using interrupts:
   a) Clear the interrupt flag bits in the respective IFSx register.
   b) Set the interrupt enable bits in the respective IECx register.
   c) Write the SPIxIP bits in the respective IPCx register to set the interrupt priority.

2. Write the desired settings to the SPIxCON1L and SPIxCON1H registers with the MSTEN bit (SPIxCON1L<5>) = 1.

3. Clear the SPIROV bit (SPIxSTATL<6>).

4. Enable SPIx operation by setting the SPIEN bit (SPIxCON1L<15>).

5. Write the data to be transmitted to the SPIxBUFL and SPIxBUFH registers. Transmission (and reception) will start as soon as data is written to the SPIxBUFL and SPIxBUFH registers.

To set up the SPIx module for the Standard Slave mode of operation:

1. Clear the SPIxBUF registers.

2. If using interrupts:
   a) Clear the SPIxBUFL and SPIxBUFH registers.
   b) Set the interrupt enable bits in the respective IECx register.
   c) Write the SPIxIP bits in the respective IPCx register to set the interrupt priority.

3. Write the desired settings to the SPIxCON1L, SPIxCON1H and SPIxCON2L registers with the MSTEN bit (SPIxCON1L<5>) = 0.

4. Clear the SMP bit.

5. If the CKE bit (SPIxCON1L<8>) is set, then the SSEN bit (SPIxCON1L<7>) must be set to enable the SSx pin.

6. Clear the SPIROV bit (SPIxSTATL<6>).

7. Enable SPIx operation by setting the SPIEN bit (SPIxCON1L<15>).

FIGURE 18-1: SPIx MODULE BLOCK DIAGRAM (STANDARD MODE)
To set up the SPIx module for the Enhanced Buffer Master mode of operation:

1. If using interrupts:
   a) Clear the interrupt flag bits in the respective IFSx register.
   b) Set the interrupt enable bits in the respective IECx register.
   c) Write the SPIxIP bits in the respective IPCx register.
2. Write the desired settings to the SPIxCON1L, SPIxCON1H and SPIxCON2L registers with MSTEN (SPIxCON1L<5>) = 1.
3. Clear the SPIROV bit (SPIxSTATL<6>).
4. Select Enhanced Buffer mode by setting the ENHBUF bit (SPIxCON1L<0>).
5. Enable SPIx operation by setting the SPIEN bit (SPIxCON1L<15>).
6. Write the data to be transmitted to the SPIxBUFL and SPIxBUFH registers. Transmission (and reception) will start as soon as data is written to the SPIxBUFL and SPIxBUFH registers.

To set up the SPIx module for the Enhanced Buffer Slave mode of operation:

1. Clear the SPIxBUFL and SPIxBUFH registers.
2. If using interrupts:
   a) Clear the interrupt flag bits in the respective IFSx register.
   b) Set the interrupt enable bits in the respective IECx register.
   c) Write the SPIxIP bits in the respective IPCx register to set the interrupt priority.
3. Write the desired settings to the SPIxCON1L, SPIxCON1H and SPIxCON2L registers with the MSTEN bit (SPIxCON1L<5>) = 0.
4. Clear the SMP bit.
5. If the CKE bit is set, then the SSEN bit must be set, thus enabling the SSx pin.
6. Clear the SPIROV bit (SPIxSTATL<6>).
7. Select Enhanced Buffer mode by setting the ENHBUF bit (SPIxCON1L<0>).
8. Enable SPIx operation by setting the SPIEN bit (SPIxCON1L<15>).

FIGURE 18-2: SPIx MODULE BLOCK DIAGRAM (ENHANCED MODE)
To set up the SPIx module for Audio mode:

1. Clear the SPIxBUFL and SPIxBUFH registers.
2. If using interrupts:
   a) Clear the interrupt flag bits in the respective IFSx register.
   b) Set the interrupt enable bits in the respective IECx register.
   a) Write the SPIxIP bits in the respective IPCx register to set the interrupt priority.
3. Write the desired settings to the SPIxCON1L, SPIxCON1H and SPIxCON2L registers with AUDEN (SPIxCON1H<15>) = 1.
4. Clear the SPIROV bit (SPIxSTATL<6>).
5. Enable SPIx operation by setting the SPIEN bit (SPIxCON1L<15>).
6. Write the data to be transmitted to the SPIxBUFL and SPIxBUFH registers. Transmission (and reception) will start as soon as data is written to the SPIxBUFL and SPIxBUFH registers.

**Note 1:** When AUDEN (SPIxCON1H<15>) = 1, this module functions as if CKE = 0, regardless of its actual value.

**Note 2:** When FRMEN = 1, SSEN is not used.

**Note 3:** MCLKEN can only be written when the SPIEN bit = 0.

**Note 4:** This channel is not meaningful for DSP/PCM mode as LRC follows FRMSYPW.
REGISTER 18-1: SPIxCON1L: SPIx CONTROL REGISTER 1 LOW (CONTINUED)

bit 9 SMP: SPIx Data Input Sample Phase bit
   Master Mode:
   1 = Input data is sampled at the end of data output time
   0 = Input data is sampled at the middle of data output time
   Slave Mode:
   Input data is always sampled at the middle of data output time, regardless of the SMP setting.

bit 8 CKE: SPIx Clock Edge Select bit(1)
   1 = Transmit happens on transition from active clock state to Idle clock state
   0 = Transmit happens on transition from Idle clock state to active clock state

bit 7 SSEN: Slave Select Enable bit (Slave mode)(2)
   1 = SSx pin is used by the macro in Slave mode; SSx pin is used as the slave select input
   0 = SSx pin is not used by the macro (SSx pin will be controlled by the port I/O)

bit 6 CKP: Clock Polarity Select bit
   1 = Idle state for clock is a high level; active state is a low level
   0 = Idle state for clock is a low level; active state is a high level

bit 5 MSTEN: Master Mode Enable bit
   1 = Master mode
   0 = Slave mode

bit 4 DISSDI: Disable SDIx Input Port bit
   1 = SDIx pin is not used by the module; pin is controlled by port function
   0 = SDIx pin is controlled by the module

bit 3 DISSCK: Disable SCKx Output Port bit
   1 = SCKx pin is not used by the module; pin is controlled by port function
   0 = SCKx pin is controlled by the module

bit 2 MCLKEN: Master Clock Enable bit(3)
   1 = REFO is used by the Baud Rate Generator (BRG)
   0 = Peripheral clock is used by the BRG

bit 1 SPIFE: Frame Sync Pulse Edge Select bit
   1 = Frame Sync pulse (Idle-to-active edge) coincides with the first bit clock
   0 = Frame Sync pulse (Idle-to-active edge) precedes the first bit clock

bit 0 ENHBUF: Enhanced Buffer Enable bit
   1 = Enhanced Buffer mode is enabled
   0 = Enhanced Buffer mode is disabled

Note 1:  When AUDEN (SPIxCON1H<15>) = 1, this module functions as if CKE = 0, regardless of its actual value.
2:  When FRMEN = 1, SSEN is not used.
3:  MCLKEN can only be written when the SPIEN bit = 0.
4:  This channel is not meaningful for DSP/PCM mode as LRC follows FRMSYPW.

U = Unimplemented bit, read as ‘0’  
-n = Value at POR  
‘1’ = Bit is set  
‘0’ = Bit is cleared  
x = Bit is unknown

---

**bit 15**  
**AUDEN:** Audio Codec Support Enable bit(1)  
1 = Audio protocol is enabled; MSTEN controls the direction of both SCKx and frame (a.k.a. LRC), and this module functions as if FRMEN = 1, FRMSYNC = MSTEN, FRMCNT<2:0> = 001 and SMP = 0, regardless of their actual values  
0 = Audio protocol is disabled

**bit 14**  
**SPISGNEXT:** SPIx Sign-Extend RX FIFO Read Data Enable bit  
1 = Data from RX FIFO is sign-extended  
0 = Data from RX FIFO is not sign-extended

**bit 13**  
**IGNROV:** Ignore Receive Overflow bit  
1 = A Receive Overflow (ROV) is NOT a critical error; during ROV, data in the FIFO is not overwritten by the receive data  
0 = A ROV is a critical error that stops SPI operation

**bit 12**  
**IGNTUR:** Ignore Transmit Underrun bit  
1 = A Transmit Underrun (TUR) is NOT a critical error and data indicated by URDTEN is transmitted until the SPIxTXB is not empty  
0 = A TUR is a critical error that stops SPI operation

**bit 11**  
**AUDMONO:** Audio Data Format Transmit bit(2)  
1 = Audio data is mono (i.e., each data word is transmitted on both left and right channels)  
0 = Audio data is stereo

**bit 10**  
**URDTEN:** Transmit Underrun Data Enable bit(3)  
1 = Transmits data out of SPIxURDT register during Transmit Underrun conditions  
0 = Transmits the last received data during Transmit Underrun conditions

**bit 9-8**  
**AUDMOD<1:0>:** Audio Protocol Mode Selection bits(4)  
11 = PCM/DSP mode  
10 = Right Justified mode: This module functions as if SPIFE = 1, regardless of its actual value  
01 = Left Justified mode: This module functions as if SPIFE = 1, regardless of its actual value  
00 = I2S mode: This module functions as if SPIFE = 0, regardless of its actual value

**bit 7**  
**FRMEN:** Framed SPIx Support bit  
1 = Framed SPIx support is enabled (SSx pin is used as the FSYNC input/output)  
0 = Framed SPIx support is disabled

**Note 1:** AUDEN can only be written when the SPIEN bit = 0.  
**2:** AUDMONO can only be written when the SPIEN bit = 0 and is only valid for AUDEN = 1.  
**3:** URDTEN is only valid when IGNTUR = 1.  
**4:** The AUDMOD<1:0> bits can only be written when the SPIEN bit = 0 and are only valid when AUDEN = 1. When NOT in PCM/DSP mode, this module functions as if FRMSYPW = 1, regardless of its actual value.
REGISTER 18-2: SPIxCON1H: SPIx CONTROL REGISTER 1 HIGH (CONTINUED)

bit 6  FRMSYNC: Frame Sync Pulse Direction Control bit
       1 = Frame Sync pulse input (slave)
       0 = Frame Sync pulse output (master)

bit 5  FRMPOL: Frame Sync/Slave Select Polarity bit
       1 = Frame Sync pulse/slave select is active-high
       0 = Frame Sync pulse/slave select is active-low

bit 4  MSSEN: Master Mode Slave Select Enable bit
       1 = SPIx slave select support is enabled with polarity determined by FRMPOL (SSx pin is automatically driven during transmission in Master mode)
       0 = Slave select SPIx support is disabled (SSx pin will be controlled by port I/O)

bit 3  FRMSYPW: Frame Sync Pulse-Width bit
       1 = Frame Sync pulse is one serial word length wide (as defined by MODE<32,16>/WLENGTH<4:0>)
       0 = Frame Sync pulse is one clock (SCK) wide

bit 2-0  FRMCNT<2:0>: Frame Sync Pulse Counter bits
       Controls the number of serial words transmitted per Sync pulse.
       111 = Reserved
       110 = Reserved
       101 = Generates a Frame Sync pulse on every 32 serial words
       100 = Generates a Frame Sync pulse on every 16 serial words
       011 = Generates a Frame Sync pulse on every 8 serial words
       010 = Generates a Frame Sync pulse on every 4 serial words
       001 = Generates a Frame Sync pulse on every 2 serial words (value used by audio protocols)
       000 = Generates a Frame Sync pulse on each serial word

Note 1: AUDEN can only be written when the SPIEN bit = 0.
Note 2: AUDMONO can only be written when the SPIEN bit = 0 and is only valid for AUDEN = 1.
Note 3: URDTEN is only valid when IGNTUR = 1.
Note 4: The AUDMOD<1:0> bits can only be written when the SPIEN bit = 0 and are only valid when AUDEN = 1.
       When NOT in PCM/DSP mode, this module functions as if FRMSYPW = 1, regardless of its actual value.

#### bit 15-13
**Unimplemented**: Read as ‘0’

#### bit 12
**FRMERR**: SPIx Frame Error Status bit
- 1 = Frame error is detected
- 0 = No frame error is detected

#### bit 11
**SPIBUSY**: SPIx Activity Status bit
- 1 = Module is currently busy with some transactions
- 0 = No ongoing transactions (at time of read)

#### bit 10-9
**Unimplemented**: Read as ‘0’

#### bit 8
**SPITUR**: SPIx Transmit Underrun Status bit(1)
- 1 = Transmit buffer has encountered a Transmit Underrun condition
- 0 = Transmit buffer does not have a Transmit Underrun condition

#### bit 7
**SRMT**: Shift Register Empty Status bit
- 1 = No current or pending transactions (i.e., neither SPIxTXB or SPIxTXSR contains data to transmit)
- 0 = Current or pending transactions

#### bit 6
**SPIROV**: SPIx Receive Overflow Status bit
- 1 = A new byte/half-word/word has been completely received when the SPIxRXB was full
- 0 = No overflow

#### bit 5
**SPIRBE**: SPIx RX Buffer Empty Status bit
- 1 = RX buffer is empty
- 0 = RX buffer is not empty

**Standard Buffer mode**:
Automatically set in hardware when SPIxBUF is read from, reading SPIxRXB. Automatically cleared in hardware when SPIx transfers data from SPIxRXSR to SPIxRXB.

**Enhanced Buffer mode**:
Indicates RXELM<5:0> = 000000.

#### bit 4
**Unimplemented**: Read as ‘0’

**Note 1**: SPITUR is cleared when SPIEN = 0. When IGNTUR = 1, SPITUR provides dynamic status of the Transmit Underrun condition, but does not stop RX/TX operation and does not need to be cleared by software.
REGISTER 18-4: SPIxSTATL: SPIx STATUS REGISTER LOW (CONTINUED)

bit 3  **SPITBE**: SPIx Transmit Buffer Empty Status bit
   1 = SPIxTXB is empty
   0 = SPIxTXB is not empty

  Standard Buffer mode:
  Automatically set in hardware when SPIx transfers data from SPIxTXB to SPIxTXSR. Automatically
  cleared in hardware when SPIxBUF is written, loading SPIxTXB.

  Enhanced Buffer mode:
  Indicates TXELM<5:0> = 000000.

bit 2  **Unimplemented**: Read as ‘0’

bit 1  **SPITBF**: SPIx Transmit Buffer Full Status bit
   1 = SPIxTXB is full
   0 = SPIxTXB not full

  Standard Buffer mode:
  Automatically set in hardware when SPIxBUF is written, loading SPIxTXB. Automatically cleared in
  hardware when SPIx transfers data from SPIxTXB to SPIxTXSR.

  Enhanced Buffer mode:
  Indicates TXELM<5:0> = 111111.

bit 0  **SPIRBF**: SPIx Receive Buffer Full Status bit
   1 = SPIxRXB is full
   0 = SPIxRXB is not full

  Standard Buffer mode:
  Automatically set in hardware when SPIx transfers data from SPIxRXSR to SPIxRXB. Automatically
  cleared in hardware when SPIxBUF is read from, reading SPIxRXB.

  Enhanced Buffer mode:
  Indicates RXELM<5:0> = 111111.

**Note 1:**  SPITUR is cleared when SPIEN = 0. When IGNTUR = 1, SPITUR provides dynamic status of the
Transmit Underrun condition, but does not stop RX/TX operation and does not need to be cleared by
software.

\]

Where:
F_{PB} is the Peripheral Bus Clock Frequency.
19.0 INTER-INTEGRATED CIRCUIT (I^2C)

Note 1: This data sheet summarizes the features of the dsPIC33EPXXXGS70X/80X family of devices. It is not intended to be a comprehensive reference source. To complement the information in this data sheet, refer to “Inter-Integrated Circuit (I^2C)” (DS70000195) in the “dsPIC33/PIC24 Family Reference Manual”, which is available from the Microchip web site (www.microchip.com).

2: Some registers and associated bits described in this section may not be available on all devices. Refer to Section 4.0 “Memory Organization” in this data sheet for device-specific register and bit information.

The dsPIC33EPXXXGS70X/80X family of devices contains two Inter-Integrated Circuit (I^2C) modules: I^2C1 and I^2C2.

The I^2C module provides complete hardware support for both Slave and Multi-Master modes of the I^2C serial communication standard, with a 16-bit interface.

The I^2C module has a 2-pin interface:
- The SCLx/ASCLx pin is clock
- The SDAx/ASDAx pin is data

The I^2C module offers the following key features:
- I^2C Interface supporting both Master and Slave modes of Operation
- I^2C Slave mode Supports 7 and 10-Bit Addressing
- I^2C Master mode Supports 7 and 10-Bit Addressing
- I^2C Port allows Bidirectional Transfers between Master and Slaves
- Serial Clock Synchronization for I^2C Port can be used as a Handshake Mechanism to Suspend and Resume Serial Transfer (SCLREL control)
- I^2C Supports Multi-Master Operation, Detects Bus Collision and Arbitrates Accordingly
- System Management Bus (SMBus) Support
- Alternate I^2C Pin Mapping (ASCLx/ASDAx)

19.1 I^2C Resources

- **HSC** = Hardware Settable/Clearable bit
- **-n** = Value at POR
- **‘1’** = Bit is set
- **U** = Unimplemented bit, read as ‘0’

**bit 15**  **ACKSTAT**: Acknowledge Status bit (when operating as I2C master, applicable to master transmit operation)

- **1** = NACK was received from slave
- **0** = ACK was received from slave

Hardware is set or cleared at the end of a slave Acknowledge.

**bit 14**  **TRSTAT**: Transmit Status bit (when operating as I2C master, applicable to master transmit operation)

- **1** = Master transmit is in progress (8 bits + ACK)
- **0** = Master transmit is not in progress

Hardware is set at the beginning of master transmission. Hardware is clear at the end of slave Acknowledge.

**bit 13**  **ACKTIM**: Acknowledge Time Status bit (I2C Slave mode only)

- **1** = I2C bus is an Acknowledge sequence, set on the 8th falling edge of SCLx
- **0** = Not an Acknowledge sequence, cleared on the 9th rising edge of SCLx

**bit 12-11**  **Unimplemented**: Read as ‘0’

**bit 10**  **BCL**: Master Bus Collision Detect bit

- **1** = A bus collision has been detected during a master operation
- **0** = No bus collision detected

Hardware is set at detection of a bus collision.

**bit 9**  **GCSTAT**: General Call Status bit

- **1** = General call address was received
- **0** = General call address was not received

Hardware is set when address matches the general call address. Hardware is clear at Stop detection.

**bit 8**  **ADD10**: 10-Bit Address Status bit

- **1** = 10-bit address was matched
- **0** = 10-bit address was not matched

Hardware is set at the match of the 2nd byte of the matched 10-bit address. Hardware is clear at Stop detection.

**bit 7**  **IWCOL**: I2Cx Write Collision Detect bit

- **1** = An attempt to write to the I2CxTRN register failed because the I2C module is busy
- **0** = No collision

Hardware is set at the occurrence of a write to I2CxTRN while busy (cleared by software).

**bit 6**  **I2COV**: I2Cx Receive Overflow Flag bit

- **1** = A byte was received while the I2CxRCV register was still holding the previous byte
- **0** = No overflow

Hardware is set at an attempt to transfer I2CxRSR to I2CxRCV (cleared by software).

**bit 5**  **D_A**: Data/Address bit (I2C Slave mode only)

- **1** = Indicates that the last byte received was data
- **0** = Indicates that the last byte received was a device address

Hardware is clear at a device address match. Hardware is set by reception of a slave byte.
REGISTER 19-3:  I2CxSTAT: I2Cx STATUS REGISTER (CONTINUED)

bit 4  P: Stop bit
1 = Indicates that a Stop bit has been detected last
0 = Stop bit was not detected last
Hardware is set or clear when a Start, Repeated Start or Stop is detected.

bit 3  S: Start bit
1 = Indicates that a Start (or Repeated Start) bit has been detected last
0 = Start bit was not detected last
Hardware is set or clear when a Start, Repeated Start or Stop is detected.

bit 2  R_W: Read/Write Information bit (I2C Slave mode only)
1 = Read – Indicates data transfer is output from the slave
0 = Write – Indicates data transfer is input to the slave
Hardware is set or clear after reception of an I2C device address byte.

bit 1  RBF: Receive Buffer Full Status bit
1 = Receive is complete, I2CxRCV is full
0 = Receive is not complete, I2CxRCV is empty
Hardware is set when I2CxRCV is written with a received byte. Hardware is clear when software reads I2CxRCV.

bit 0  TBF: Transmit Buffer Full Status bit
1 = Transmit is in progress, I2CxTRN is full
0 = Transmit is complete, I2CxTRN is empty
Hardware is set when software writes to I2CxTRN. Hardware is clear at completion of a data transmission.

For 7-Bit Address (I2CxMSK<6:0> only):
- **1** = Enables masking for bit Ax + 1 of incoming message address; bit match is not required in this position
- **0** = Disables masking for bit Ax + 1; bit match is required in this position
20.0 UNIVERSAL ASYNCHRONOUS RECEIVER TRANSMITTER (UART)

The dsPIC33EPXXXGS70X/80X family of devices contains two UART modules.

The Universal Asynchronous Receiver Transmitter (UART) module is one of the serial I/O modules available in the dsPIC33EPXXXGS70X/80X device family. The UART is a full-duplex, asynchronous system that can communicate with peripheral devices, such as personal computers, LIN/J2602, RS-232 and RS-485 interfaces. The module also supports a hardware flow control option with the UxCTS and UxRTS pins, and also includes an IrDA® encoder and decoder.

The primary features of the UARTx module are:
- Full-Duplex, 8 or 9-Bit Data Transmission through the UxTX and UxRX Pins
- Even, Odd or No Parity Options (for 8-bit data)
- One or Two Stop bits
- Hardware Flow Control Option with UxCTS and UxRTS Pins
- Fully Integrated Baud Rate Generator with 16-Bit Prescaler
- Baud Rates Ranging from 4.375 Mbps to 67 bps in 16x mode at 70 MIPS
- Baud Rates Ranging from 17.5 Mbps to 267 bps in 4x mode at 70 MIPS
- 4-Deep First-In First-Out (FIFO) Transmit Data Buffer
- 4-Deep FIFO Receive Data Buffer
- Parity, Framing and Buffer Overrun Error Detection
- Support for 9-Bit mode with Address Detect (9th bit = 1)
- Transmit and Receive Interrupts
- A Separate Interrupt for all UARTx Error Conditions
- Loopback mode for Diagnostic Support
- Support for Sync and Break Characters
- Support for Automatic Baud Rate Detection
- IrDA® Encoder and Decoder Logic
- 16x Baud Clock Output for IrDA Support

A simplified block diagram of the UARTx module is shown in Figure 20-1. The UARTx module consists of these key hardware elements:
- Baud Rate Generator
- Asynchronous Transmitter
- Asynchronous Receiver

Note 1: This data sheet summarizes the features of the dsPIC33EPXXXGS70X/80X family of devices. It is not intended to be a comprehensive reference source. To complement the information in this data sheet, refer to “Universal Asynchronous Receiver Transmitter (UART)” (DS70000582) in the “dsPIC33/PIC24 Family Reference Manual”, which is available from the Microchip web site (www.microchip.com).

Note 2: Some registers and associated bits described in this section may not be available on all devices. Refer to Section 4.0 “Memory Organization” in this data sheet for device-specific register and bit information.
20.1 UART Helpful Tips

1. In multi-node, direct connect UART networks, UART receive inputs react to the complementary logic level defined by the URXINV bit (UXMODE<4>), which defines the Idle state, the default of which is logic high (i.e., URXINV = 0). Because remote devices do not initialize at the same time, it is likely that one of the devices, because the RX line is floating, will trigger a Start bit detection and will cause the first byte received, after the device has been initialized, to be invalid. To avoid this situation, the user should use a pull-up or pull-down resistor on the RX pin depending on the value of the URXINV bit.
   a) If URXINV = 0, use a pull-up resistor on the UxRX pin.
   b) If URXINV = 1, use a pull-down resistor on the UxRX pin.

2. The first character received on a wake-up from Sleep mode, caused by activity on the UxRX pin of the UARTx module, will be invalid. In Sleep mode, peripheral clocks are disabled. By the time the oscillator system has restarted and stabilized from Sleep mode, the baud rate bit sampling clock, relative to the incoming UxRX bit timing, is no longer synchronized, resulting in the first character being invalid; this is to be expected.

20.2 UART Resources

Many useful resources are provided on the main product page of the Microchip web site for the devices listed in this data sheet. This product page contains the latest updates and additional information.

- x = Bit is unknown

1: Refer to “Universal Asynchronous Receiver Transmitter (UART)” (DS70000582) in the “dsPIC33/PIC24 Family Reference Manual” for information on enabling the UARTx module for receive or transmit operation.

2: This feature is only available for the 16x BRG mode (BRGH = 0).
REGISTER 20-1:  UxMODE: UARTx MODE REGISTER (CONTINUED)

bit 5  **ABAUD**: Auto-Baud Enable bit
  1 = Enables baud rate measurement on the next character – requires reception of a Sync field (55h) before other data; cleared in hardware upon completion
  0 = Baud rate measurement is disabled or completed

bit 4  **URXINV**: UARTx Receive Polarity Inversion bit
  1 = UxRX Idle state is ‘0’
  0 = UxRX Idle state is ‘1’

bit 3  **BRGH**: High Baud Rate Enable bit
  1 = BRG generates 4 clocks per bit period (4x baud clock, High-Speed mode)
  0 = BRG generates 16 clocks per bit period (16x baud clock, Standard mode)

bit 2-1  **PDSEL<1:0>**: Parity and Data Selection bits
  11 = 9-bit data, no parity
  10 = 8-bit data, odd parity
  01 = 8-bit data, even parity
  00 = 8-bit data, no parity

bit 0  **STSEL**: Stop Bit Selection bit
  1 = Two Stop bits
  0 = One Stop bit

Note 1: Refer to “Universal Asynchronous Receiver Transmitter (UART)” (DS70000582) in the “dsPIC33/PIC24 Family Reference Manual” for information on enabling the UARTx module for receive or transmit operation.

2: This feature is only available for the 16x BRG mode (BRGH = 0).

- ‘0’ = Bit is cleared
- x = Bit is unknown

**Note 1:** Refer to “Universal Asynchronous Receiver Transmitter (UART)” (DS70000582) in the “dsPIC33/PIC24 Family Reference Manual” for information on enabling the UARTx module for transmit operation.
REGISTER 20-2:  UxSTA: UARTx STATUS AND CONTROL REGISTER (CONTINUED)

bit 5  **ADDEN:** Address Character Detect bit (bit 8 of received data = 1)
       1 = Address Detect mode is enabled; if 9-bit mode is not selected, this does not take effect
       0 = Address Detect mode is disabled

bit 4  **RIDLE:** Receiver Idle bit (read-only)
       1 = Receiver is Idle
       0 = Receiver is active

bit 3  **PERR:** Parity Error Status bit (read-only)
       1 = Parity error has been detected for the current character (character at the top of the receive FIFO)
       0 = Parity error has not been detected

bit 2  **FERR:** Framing Error Status bit (read-only)
       1 = Framing error has been detected for the current character (character at the top of the receive FIFO)
       0 = Framing error has not been detected

bit 1  **OERR:** Receive Buffer Overrun Error Status bit (clear/read-only)
       1 = Receive buffer has overflowed
       0 = Receive buffer has not overflowed; clearing a previously set OERR bit (1 → 0 transition) resets the
           receiver buffer and the UxRSR to the empty state

bit 0  **URXDA:** UARTx Receive Buffer Data Available bit (read-only)
       1 = Receive buffer has data, at least one more character can be read
       0 = Receive buffer is empty

**Note 1:** Refer to “Universal Asynchronous Receiver Transmitter (UART)” (DS70000582) in the “dsPIC33/PIC24 Family Reference Manual” for information on enabling the UARTx module for transmit operation.
21.0 CONFIGURABLE LOGIC CELL (CLC)

The Configurable Logic Cell (CLC) module allows the user to specify combinations of signals as inputs to a logic function and to use the logic output to control other peripherals or I/O pins. This provides greater flexibility and potential in embedded designs since the CLC module can operate outside the limitations of software execution and supports a vast amount of output designs.

There are four input gates to the selected logic function. These four input gates select from a pool of up to 32 signals that are selected using four data source selection multiplexers. Figure 21-1 shows an overview of the module. Figure 21-3 shows the details of the data source multiplexers and logic input gate connections.

Note: This data sheet summarizes the features of the dsPIC33EPXXXGS70X/80X family devices. It is not intended to be a comprehensive reference source. To complement the information in this data sheet, refer to “Configurable Logic Cell (CLC)” (DS70005298) in the “dsPIC33/PIC24 Family Reference Manual”, which is available from the Microchip web site (www.microchip.com).

FIGURE 21-3: CLCx INPUT SOURCE SELECTION DIAGRAM

Note: All controls are undefined at power-up.
21.1 Control Registers

The CLCx module is controlled by the following registers:

- CLCxCONL
- CLCxCONH
- CLCxSEL
- CLCxGSL
- CLCxGLSH

The CLCx Control registers (CLCxCONL and CLCxCONH) are used to enable the module and interrupts, control the output enable bit, select output polarity and select the logic function. The CLCx Control registers also allow the user to control the logic polarity of not only the cell output, but also some intermediate variables.

The CLCx Input MUX Select register (CLCxSEL) allows the user to select up to 4 data input sources using the 4 data input selection multiplexers. Each multiplexer has a list of 8 data sources available.

The CLCx Gate Logic Input Select registers (CLCxGSL and CLCxGLSH) allow the user to select which outputs from each of the selection MUXes are used as inputs to the input gates of the logic cell. Each data source MUX outputs both a true and a negated version of its output. All of these 8 signals are enabled, ORed together by the logic cell input gates.

22.0 HIGH-SPEED, 12-BIT ANALOG-TO-DIGITAL CONVERTER (ADC)

<table>
<thead>
<tr>
<th>Note 1:</th>
<th>This data sheet summarizes the features of the dsPIC33EPXXXGS70X/80X family of devices. It is not intended to be a comprehensive reference source. To complement the information in this data sheet, refer to “12-Bit High-Speed, Multiple SARs A/D Converter (ADC)” (DS70005213) in the “dsPIC33/PIC24 Family Reference Manual”, which is available from the Microchip web site (<a href="http://www.microchip.com">www.microchip.com</a>).</th>
</tr>
</thead>
</table>
2: Some registers and associated bits described in this section may not be available on all devices. Refer to Section 4.0 “Memory Organization” in this data sheet for device-specific register and bit information.

dsPIC33EPXXXGS70X/80X devices have a high-speed, 12-bit Analog-to-Digital Converter (ADC) that features a low conversion latency, high resolution and oversampling capabilities to improve performance in AC/DC, DC/DC power converters.

22.1 Features Overview

The high-speed, 12-bit multiple SARs Analog-to-Digital Converter (ADC) includes the following features:

- Five ADC Cores: Four Dedicated Cores and One Shared (common) Core
- User-Configurable Resolution of up to 12 Bits for each Core
- Up to 3.25 Msps Conversion Rate per Channel at 12-Bit Resolution
- Low Latency Conversion
- Up to 22 Analog Input Channels, with a Separate 16-Bit Conversion Result Register for each Input
- Conversion Result can be Formatted as Unsigned or Signed Data, on a per Channel Basis, for All Channels
- Single-Ended and Pseudodifferential Conversions are available on All ADC Cores
- Simultaneous Sampling of up to 5 Analog Inputs
- Channel Scan Capability
- Multiple Conversion Trigger Options for each Core, including:
  - PWM1 through PWM6 (primary and secondary triggers, and current-limit event trigger)
  - PWM Special Event Trigger
  - Timer1/Timer2 period match
  - Output Compare 1 and event trigger
  - External pin trigger event (ADTRG31)
  - Software trigger
- Two Integrated Digital Comparators with Dedicated Interrupts:
  - Multiple comparison options
  - Assignable to specific analog inputs
- Two Oversampling Filters with Dedicated Interrupts:
  - Provide increased resolution
  - Assignable to a specific analog input

The module consists of five independent SAR ADC cores. Simplified block diagrams of the multiple SARs 12-bit ADC are shown in Figure 22-1, Figure 22-2 and Figure 22-3.

The analog inputs (channels) are connected through multiplexers and switches to the Sample-and-Hold (S&H) circuit of each ADC core. The core uses the channel information (the output format, the Measurement mode and the input number) to process the analog sample. When conversion is complete, the result is stored in the result buffer for the specific analog input, and passed to the digital filter and digital comparator if they were configured to use data from this particular channel.

The ADC module can sample up to five inputs at a time (four inputs from the dedicated SAR cores and one from the shared SAR core). If multiple ADC inputs request conversion on the shared core, the module will convert them in a sequential manner, starting with the lowest order input.

The ADC provides each analog input the ability to specify its own trigger source. This capability allows the ADC to sample and convert analog inputs that are associated with PWM generators operating on independent time bases.
FIGURE 22-1: ADC MODULE BLOCK DIAGRAM

Note 1: PGA1, PGA2 and the Band Gap Reference (Vbg) are internal analog inputs and are not available on device pins.

2: If the dedicated core uses an alternate channel, then shared core function cannot be used.
FIGURE 22-2: DEDICATED ADC CORES 0 TO 3 BLOCK DIAGRAM

Note 1: The DIFFx bit for the corresponding positive input channel must be set in order to use the negative differential input.

FIGURE 22-3: SHARED ADC CORE BLOCK DIAGRAM

Note 1: Differential-mode conversion is not available for the shared ADC core in dsPIC33EPXXGS70X/80X devices. For all other devices, the DIFFx bit for the corresponding positive input channel must be set to use AN9 as the negative differential input.
22.2 Analog-to-Digital Converter Resources

Many useful resources are provided on the main product page of the Microchip web site for the devices listed in this data sheet. This product page contains the latest updates and additional information.

22.2.1 KEY RESOURCES

- “12-Bit High-Speed, Multiple SARs A/D Converter (ADC)” (DS70005213) in the “dsPIC33/PIC24 Family Reference Manual”
- Code Samples
- Application Notes
- Software Libraries
- Webinars
- All Related “dsPIC33/PIC24 Family Reference Manual” Sections

  - **Value**: 001=111 = **Unimplemented**: Do not use

- **bit 12**
  - **SUSPEND**: All ADC Cores Triggers Disable bit
    - 1 = All new trigger events for all ADC cores are disabled
    - 0 = All ADC cores can be triggered

- **bit 11**
  - **SUSPCIE**: Suspend All ADC Cores Common Interrupt Enable bit
    - 1 = Common interrupt will be generated when ADC core triggers are suspended (SUSPEND bit = 1) and all previous conversions are finished (SUSPRDY bit becomes set)
    - 0 = Common interrupt is not generated for suspend ADC cores event

- **bit 10**
  - **SUSPRDY**: All ADC Cores Suspended Flag bit
    - 1 = All ADC cores are suspended (SUSPEND bit = 1) and have no conversions in progress
    - 0 = ADC cores have previous conversions in progress

- **bit 9**
  - **SHRSAMP**: Shared ADC Core Sampling Direct Control bit
    - This bit should be used with the individual channel conversion trigger controlled by the CNVRTCH bit. It connects an analog input, specified by the CNVCHSEL<5:0> bits, to the shared ADC core and allows extending the sampling time. This bit is not controlled by hardware and must be cleared before the conversion starts (setting CNVRTCH to ‘1’).
    - 1 = Shared ADC core samples an analog input specified by the CNVCHSEL<5:0> bits
    - 0 = Sampling is controlled by the shared ADC core hardware

- **bit 8**
  - **CNVRTCH**: Software Individual Channel Conversion Trigger bit
    - 1 = Single trigger is generated for an analog input specified by the CNVCHSEL<5:0> bits; when the bit is set, it is automatically cleared by hardware on the next instruction cycle
    - 0 = Next individual channel conversion trigger can be generated

- **bit 7**
  - **SWLCTRG**: Software Level-Sensitive Common Trigger bit
    - 1 = Triggers are continuously generated for all channels with the software, level-sensitive common trigger selected as a source in the ADTRIGxL and ADTRIGxH registers
    - 0 = No software, level-sensitive common triggers are generated

- **bit 6**
  - **SWCTRG**: Software Common Trigger bit
    - 1 = Single trigger is generated for all channels with the software, common trigger selected as a source in the ADTRIGxL and ADTRIGxH registers; when the bit is set, it is automatically cleared by hardware on the next instruction cycle
    - 0 = Ready to generate the next software common trigger

- **bit 5-0**
  - **CNVCHSEL<5:0>:** Channel Number Selection for Software Individual Channel Conversion Trigger bits
    - These bits define a channel to be converted when the CNVRTCH bit is set.

23.0 CONTROLLER AREA NETWORK (CAN) MODULE
(dsPIC33EPXXXGS80X DEVICES ONLY)

Note 1: This data sheet summarizes the features of the dsPIC33EPXXXGS70X/80X family of devices. It is not intended to be a comprehensive reference source. To complement the information in this data sheet, refer to “Enhanced Controller Area Network (ECAN)” (DS70353) in the “dsPIC33/PIC24 Family Reference Manual”, which is available from the Microchip web site (www.microchip.com).

Note 2: Some registers and associated bits described in this section may not be available on all devices. Refer to Section 4.0 “Memory Organization” in this data sheet for device-specific register and bit information.

23.1 Overview

The Controller Area Network (CAN) module is a serial interface, useful for communicating with other CAN modules or microcontroller devices. This interface/protocol was designed to allow communications within noisy environments. The dsPIC33EPXXXGS80X devices contain two CAN modules.

The CAN module is a communication controller, implementing the CAN 2.0 A/B protocol, as defined in the BOSCH CAN specification. The module supports CAN 1.2, CAN 2.0A, CAN 2.0B Passive and CAN 2.0B Active versions of the protocol. The module implementation is a full CAN system. The CAN specification is not covered within this data sheet. The reader can refer to the BOSCH CAN specification for further details.

The CAN module features are as follows:
- Implementation of the CAN Protocol, CAN 1.2, CAN 2.0A and CAN 2.0B
- Standard and Extended Data Frames
- 0-8 Bytes of Data Length
- Programmable Bit Rate, up to 1 Mbit/sec
- Automatic Response to Remote Transmission Requests
- Up to 8 Transmit Buffers with Application Specified Prioritization and Abort Capability (each buffer can contain up to 8 bytes of data)
- Up to 32 Receive Buffers (each buffer can contain up to 8 bytes of data)
- Up to 16 Full (Standard/Extended Identifier) Acceptance Filters
- Three Full Acceptance Filter Masks
- DeviceNet™ Addressing Support
- Programmable Wake-up Functionality with Integrated Low-Pass Filter
- Programmable Loopback mode supports Self-Test Operation
- Signaling via Interrupt Capabilities for All CAN Receiver and Transmitter Error States
- Programmable Clock Source
- Programmable Link to Input Capture 2 (IC2) module for Timestamping and Network Synchronization
- Low-Power Sleep and Idle modes

The CAN bus module consists of a protocol engine and message buffering/control. The CAN protocol engine handles all functions for receiving and transmitting messages on the CAN bus. Messages are transmitted by first loading the appropriate data registers. Status and errors can be checked by reading the appropriate registers. Any message detected on the CAN bus is checked for errors and then matched against filters to see if it should be received and stored in one of the receive registers.
23.2 Modes of Operation

The CANx module can operate in one of several operation modes selected by the user. These modes include:

- Initialization mode
- Disable mode
- Normal Operation mode
- Listen Only mode
- Listen All Messages mode
- Loopback mode

Modes are requested by setting the REQOP<2:0> bits (CxCTRL1<10:8>). Entry into a mode is Acknowledged by monitoring the OPMODE<2:0> bits (CxCTRL1<7:5>). The module does not change the mode and the OPMODEx bits until a change in mode is acceptable, generally during bus Idle time, which is defined as at least 11 consecutive recessive bits.

bit 12-8   **FILHIT<4:0>:** Filter Hit Code bits\(^{(1)}\)
Encodes number of filter that resulted in writing this buffer.
bit 7-0    **Unimplemented**: Read as ‘0’

Note 1: Only written by module for receive buffers, unused for transmit buffers.
24.0 HIGH-SPEED ANALOG COMPARATOR

Note 1: This data sheet summarizes the features of the dsPIC33EPXXXGS70X/80X family of devices. It is not intended to be a comprehensive reference source. To complement the information in this data sheet, refer to “High-Speed Analog Comparator Module” (DS70005128) in the “dsPIC33/PIC24 Family Reference Manual”, which is available from the Microchip web site (www.microchip.com).

2: Some registers and associated bits described in this section may not be available on all devices. Refer to Section 4.0 “Memory Organization” in this data sheet for device-specific register and bit information.

The high-speed analog comparator module monitors current and/or voltage transients that may be too fast for the CPU and ADC to capture.

24.1 Features Overview

The Switch Mode Power Supply (SMPS) comparator module offers the following major features:

- Four Rail-to-Rail Analog Comparators
- Dedicated 12-Bit DAC for each Analog Comparator
- Up to Six Selectable Input Sources per Comparator:
  - Four external inputs
  - Two internal inputs from the PGAx module
- Programmable Comparator Hysteresis
- Programmable Output Polarity
- Up to Two DAC Outputs to Device Pins
- Multiple Voltage References for the DAC:
  - External References (EXTREF1 or EXTREF2)
  - AVDD
- Interrupt Generation Capability
- Functional Support for PWMx:
  - PWMx duty cycle control
  - PWMx period control
  - PWMx Fault detected
24.2 Module Description

Figure 24-1 shows a functional block diagram of one analog comparator from the high-speed analog comparator module. The analog comparator provides high-speed operation with a typical delay of 15 ns. The negative input of the comparator is always connected to the DACx circuit. The positive input of the comparator is connected to an analog multiplexer that selects the desired source pin.

The analog comparator input pins are typically shared with pins used by the Analog-to-Digital Converter (ADC) module. Both the comparator and the ADC can use the same pins at the same time. This capability enables a user to measure an input voltage with the ADC and detect voltage transients with the comparator.

FIGURE 24-1: HIGH-SPEED ANALOG COMPARATOR x MODULE BLOCK DIAGRAM

Note 1: \( x = 1-4 \)

2: EXTREF1 is connected to DAC1/DAC3. EXTREF2 is connected to DAC2/DAC4.

3: Not available on all devices.
24.3 Module Applications

This module provides a means for the SMPS dsPIC® DSC devices to monitor voltage and currents in a power conversion application. The ability to detect transient conditions and stimulate the dsPIC DSC processor and/or peripherals, without requiring the processor and ADC to constantly monitor voltages or currents, frees the dsPIC DSC to perform other tasks.

The comparator module has a high-speed comparator and an associated 12-bit DAC that provides a programmable reference voltage to the inverting input of the comparator. The polarity of the comparator output is user-programmable. The output of the module can be used in the following modes:

- Generate an Interrupt
- Trigger an ADC Sample and Convert Process
- Truncate the PWMx Signal (current limit)
- Truncate the PWMx Period (current minimum)
- Disable the PWMx Outputs (Fault latch)

The output of the comparator module may be used in multiple modes at the same time, such as: 1) generate an interrupt, 2) have the ADC take a sample and convert it, and 3) truncate the PWMx output in response to a voltage being detected beyond its expected value.

The comparator module can also be used to wake-up the system from Sleep or Idle mode when the analog input voltage exceeds the programmed threshold voltage.

24.4 Digital-to-Analog Comparator (DAC)

Each analog comparator has a dedicated 12-bit DAC that is used to program the comparator threshold voltage via the CMPxDAC register. The DAC voltage reference source is selected using the EXTREF and RANGE bits in the CMPxCON register.

The EXTREF bit selects either the external voltage reference, EXTREFx, or an internal source as the voltage reference source. The EXTREFx input enables users to connect to a voltage reference that better suits their application. The RANGE bit enables AVDD as the voltage reference source for the DAC when an internal voltage reference is selected.

Note: EXTREF2 is not available on all devices.

Each DACx has an output enable bit, DACOE, in the CMPxCON register that enables the DACx reference voltage to be routed to an external output pin (DACOUTx). Refer to Figure 24-1 for connecting the DACx output voltage to the DACOUTx pins.

Note 1: Ensure that multiple DACOE bits are not set in software. The output on the DACOUTx pin will be indeterminate if multiple comparators enable the DACx output.

2: DACOUT2 is not available on all devices.

24.5 Pulse Stretcher and Digital Logic

The analog comparator can respond to very fast transient signals. After the comparator output is given the desired polarity, the signal is passed to a pulse stretching circuit. The pulse stretching circuit has an asynchronous set function and a delay circuit that ensures the minimum pulse width is three system clock cycles wide to allow the attached circuitry to properly respond to a narrow pulse event.

The pulse stretcher circuit is followed by a digital filter. The digital filter is enabled via the FLTREN bit in the CMPxCON register. The digital filter operates with the clock specified via the FCLKSEL bit in the CMPxCON register. The comparator signal must be stable in a high or low state, for at least three of the selected clock cycles, for it to pass through the digital filter.

Note: EXTREF2 is not available on all devices.
24.6 Hysteresis

An additional feature of the module is hysteresis control. Hysteresis can be enabled or disabled and its amplitude can be controlled by the HYSSEL<1:0> bits in the CMPxCON register. Three different values are available: 15 mV, 30 mV and 45 mV. It is also possible to select the edge (rising or falling) to which hysteresis is to be applied.

Hysteresis control prevents the comparator output from continuously changing state because of small perturbations (noise) at the input (see Figure 24-2).

FIGURE 24-2: HYSTERESIS CONTROL

24.7 Analog Comparator Resources

Many useful resources are provided on the main product page of the Microchip web site for the devices listed in this data sheet. This product page contains the latest updates and additional information.

25.0 PROGRAMMABLE GAIN AMPLIFIER (PGA)

The dsPIC33EPXXXGS70X/80X family devices have two Programmable Gain Amplifiers (PGA1, PGA2). The PGA is an op amp-based, non-inverting amplifier with user-programmable gains. The output of the PGA can be connected to a number of dedicated Sample-and-Hold inputs of the Analog-to-Digital Converter and/or to the high-speed analog comparator module. The PGA has five selectable gains and may be used as a ground referenced amplifier (single-ended) or used with an independent ground reference point.

Key features of the PGA module include:
- Single-Ended or Independent Ground Reference
- Selectable Gains: 4x, 8x, 16x, 32x and 64x
- High Gain Bandwidth
- Rail-to-Rail Output Voltage
- Wide Input Voltage Range

FIGURE 25-1: PGAx MODULE BLOCK DIAGRAM

Note 1: This data sheet summarizes the features of the dsPIC33EPXXXGS70X/80X family of devices. It is not intended to be a comprehensive reference source. To complement the information in this data sheet, refer to “Programmable Gain Amplifier (PGA)” (DS70005146) in the “dsPIC33/PIC24 Family Reference Manual”, which is available from the Microchip web site (www.microchip.com).

2: Some registers and associated bits described in this section may not be available on all devices. Refer to Section 4.0 “Memory Organization” in this data sheet for device-specific register and bit information.

Note 1: x = 1 and 2.
25.1 Module Description

The Programmable Gain Amplifiers are used to amplify small voltages (i.e., voltages across burden/shunt resistors) to improve the signal-to-noise ratio of the measured signal. The PGAx output voltage can be read by any of the four dedicated Sample-and-Hold circuits on the ADC module. The output voltage can also be fed to the comparator module for overcurrent/voltage protection. Figure 25-2 shows a functional block diagram of the PGAx module. Refer to Section 22.0 “High-Speed, 12-Bit Analog-to-Digital Converter (ADC)” and Section 24.0 “High-Speed Analog Comparator” for more interconnection details.

The gain of the PGAx module is selectable via the GAIN<2:0> bits in the PGAxCON register. There are five selectable gains, ranging from 4x to 64x. The SELPI<2:0> and SELNI<2:0> bits in the PGAxCON register select one of four positive/negative inputs to the PGAx module. For single-ended applications, the SELNI<2:0> bits will select the ground as the negative input source. To provide an independent ground reference, the PGAxN2 and PGAxN3 pins are available as the negative input source to the PGAx module.

Note 1: Not all PGA positive/negative inputs are available on all devices. Refer to the specific device pinout for available input source pins.

The output voltage of the PGAx module can be connected to the DACOUTx pin by setting the PGAOEN bit in the PGAxCON register. When the PGAOEN bit is enabled, the output voltage of PGA1 is connected to DACOUT1 and PGA2 is connected to DACOUT2. For devices with a single DACOUTx pin, the output voltage of PGA2 can be connected to DACOUT1 by configuring the DBCC Configuration bit in the FDEVOPT register (FDEVOPT<6>.

If both the DACx output voltage and PGAx output voltage are connected to the DACOUTx pin, the resulting output voltage would be a combination of signals. There is no assigned priority between the PGAx module and the DACx module.

Note 1: x = 1 and 2.
2: The DACOUT2 device pin is only available on 64-pin devices.
3: The PGAxN3 input is not available on 28-pin devices.

bit 5-0  PGACAL<5:0>: PGAx Offset Calibration bits

The calibration values for PGA1 and PGA2 must be copied from Flash addresses, 0x800E48 and 0x800E4C, respectively, into these bits before the module is enabled. Refer to the calibration data address table (Table 27-3) in Section 27.0 “Special Features” for more information.
26.0 CONSTANT-CURRENT SOURCE

The constant-current source module is a precision current generator and is used in conjunction with the ADC module to measure the resistance of external resistors connected to device pins.

26.1 Features Overview

The constant-current source module offers the following major features:

- Constant-Current Generator (10 µA nominal)
- Internal Selectable Connection to One of Four Pins
- Enable/Disable bit

26.2 Module Description

Figure 26-1 shows a functional block diagram of the constant-current source module. It consists of a precision current generator with a nominal value of 10 µA. The module can be enabled and disabled using the ISRCEN bit in the ISRCCON register. The output of the current generator is internally connected to a device pin. The dsPIC33EPXXXGS70X/80X family can have up to 4 selectable current source pins. The OUTSEL<2:0> bits in the ISRCCON register allow selection of the target pin.

The current source is calibrated during testing.

FIGURE 26-1: CONSTANT-CURRENT SOURCE MODULE BLOCK DIAGRAM

Note 1: This data sheet summarizes the features of the dsPIC33EPXXXGS70X/80X family of devices. It is not intended to be a comprehensive reference source. To complement the information in this data sheet, refer to the related section of the “dsPIC33/PIC24 Family Reference Manual”, which is available from the Microchip web site (www.microchip.com).

2: Some registers and associated bits described in this section may not be available on all devices. Refer to Section 4.0 “Memory Organization” in this data sheet for device-specific register and bit information.

27.0 SPECIAL FEATURES

The dsPIC33EPXXXGS70X/80X family devices include several features intended to maximize application flexibility and reliability, and minimize cost through elimination of external components. These are:

- Flexible Configuration
- Watchdog Timer (WDT)
- Code Protection and CodeGuard™ Security
- JTAG Boundary Scan Interface
- In-Circuit Serial Programming™ (ICSP™)
- In-Circuit Emulation
- Brown-out Reset (BOR)

Note: This data sheet summarizes the features of the dsPIC33EPXXXGS70X/80X family of devices. It is not intended to be a comprehensive reference source. To complement the information in this data sheet, refer to “Device Configuration” (DS70000618), “Watchdog Timer and Power-Saving Modes” (DS70615) and “CodeGuard™ Intermediate Security” (DS70005182) in the “dsPIC33/PIC24 Family Reference Manual”, which is available from the Microchip web site (www.microchip.com).

27.1 Configuration Bits

In dsPIC33EPXXXGS70X/80X family devices, the Configuration Words are implemented as volatile memory. This means that configuration data must be programmed each time the device is powered up. Configuration data is stored at the end of the on-chip program memory space, known as the Flash Configuration Words. Their specific locations are shown in Table 27-1 with detailed descriptions in Table 27-2. The configuration data is automatically loaded from the Flash Configuration Words to the proper Configuration Shadow registers during device Resets.

For devices operating in Dual Partition Flash modes, the BSEQx bits (FBTSEQ<11:0>) determine which panel is the Active Partition at start-up and the Configuration Words from that panel are loaded into the Configuration Shadow registers.

Note: Configuration data is reloaded on all types of device Resets.

When creating applications for these devices, users should always specifically allocate the location of the Flash Configuration Words for configuration data in their code for the compiler. This is to make certain that program code is not stored in this address when the code is compiled. Program code executing out of configuration space will cause a device Reset.

Note: Performing a page erase operation on the last page of program memory clears the Flash Configuration Words.

**Note 1:** These bits are reserved and must be programmed as '1'.

**Note 2:** This bit is reserved and must be programmed as '0'.

**Note 3:** When operating in Dual Partition Flash mode, each partition will have dedicated Configuration registers. On a device Reset, the configuration values of the Active Partition are read at start-up, but during a soft swap condition, the configuration settings of the newly Active Partition are ignored.

**Note 4:** FBOOT resides in configuration memory space.

27.2 Device Calibration and Identification

The PGAx and current source modules on the dsPIC33EPXXXGS70X/80X family devices require Calibration Data registers to improve performance of the module over a wide operating range. These Calibration registers are read-only and are stored in configuration memory space. Prior to enabling the module, the calibration data must be read (TBLPAG and Table Read instruction) and loaded into its respective SFR registers. The device calibration addresses are shown in Table 27-3.

The dsPIC33EPXXXGS70X/80X devices have two Identification registers near the end of configuration memory space that store the Device ID (DEVID) and Device Revision (DEVREV). These registers are used to determine the mask, variant and manufacturing information about the device. These registers are read-only and are shown in Register 27-1 and Register 27-2.

27.3 User OTP Memory
The dsPIC33EPXXXGS70X/80X family devices contain 64 words of user One-Time-Programmable (OTP) memory located at addresses, 0x800F80 through 0x800FFC. The user OTP Words can be used for storing checksum, code revisions, product information, such as serial numbers, system manufacturing dates, manufacturing lot numbers and other application-specific information. These words can only be written once at program time and not at run time; they can be read at run time.

27.4 On-Chip Voltage Regulator
All the dsPIC33EPXXXGS70X/80X family devices power their core digital logic at a nominal 1.8V. This can create a conflict for designs that are required to operate at a higher typical voltage, such as 3.3V. To simplify system design, all devices in the dsPIC33EPXXXGS70X/80X family incorporate an on-chip regulator that allows the device to run its core logic from VDD.

The regulator provides power to the core from the other VDD pins. A low-ESR (less than 1 Ohm) capacitor (such as tantalum or ceramic) must be connected to the VCAP pin (Figure 27-1). This helps to maintain the stability of the regulator. The recommended value for the filter capacitor is provided in Table 30-5, located in Section 30.0 “Electrical Characteristics”.

Note: It is important for the low-ESR capacitor to be placed as close as possible to the VCAP pin.

FIGURE 27-1: CONNECTIONS FOR THE ON-CHIP VOLTAGE REGULATOR(1,2,3)

27.5 Brown-out Reset (BOR)
The Brown-out Reset (BOR) module is based on an internal voltage reference circuit that monitors the regulated supply voltage, VCAP. The main purpose of the BOR module is to generate a device Reset when a brown-out condition occurs. Brown-out conditions are generally caused by glitches on the AC mains (for example, missing portions of the AC cycle waveform due to bad power transmission lines or voltage sags due to excessive current draw when a large inductive load is turned on).

A BOR generates a Reset pulse which resets the device. The BOR selects the clock source based on the device Configuration bit values (FNOSC<2:0> and POSCMD<1:0>).

If an Oscillator mode is selected, the BOR activates the Oscillator Start-up Timer (OST). The system clock is held until OST expires. If the PLL is used, the clock is held until the LOCK bit (OSCCON<5>) is '1'.

Concurrently, the Power-up Timer (PWRT) Time-out (TPWRT) is applied before the internal Reset is released. If TPWRT = 0 and a crystal oscillator is being used, then a nominal delay of TFSCM is applied. The total delay in this case is TFSCM. Refer to Parameter SY35 in Table 30-23 of Section 30.0 “Electrical Characteristics” for specific TFSCM values.

The BOR status bit (RCON<1>) is set to indicate that a BOR has occurred. The BOR circuit continues to operate while in Sleep or Idle modes and resets the device should VDD fall below the BOR threshold voltage.

Note: It is important for the low-ESR capacitor to be placed as close as possible to the VCAP pin.

Note 1: These are typical operating voltages. Refer to Table 30-5 located in Section 30.0 “Electrical Characteristics” for the full operating ranges of VDD and VCAP.

2: It is important for the low-ESR capacitor to be placed as close as possible to the VCAP pin.

3: Typical VCAP pin voltage = 1.8V when VDD ≥ VDDMIN.
27.6 Watchdog Timer (WDT)

For dsPIC33EPXXXGS70X/80X family devices, the WDT is driven by the LPRC oscillator. When the WDT is enabled, the clock source is also enabled.

27.6.1 PRESCALER/POSTSCALER

The nominal WDT clock source from LPRC is 32 kHz. This feeds a prescaler that can be configured for either 5-bit (divide-by-32) or 7-bit (divide-by-128) operation. The prescaler is set by the WDTPRE Configuration bit. With a 32 kHz input, the prescaler yields a WDT Time-out Period (TWDT), as shown in Parameter SY12 in Table 30-23.

A variable postscaler divides down the WDT prescaler output and allows for a wide range of time-out periods. The postscaler is controlled by the WDTPR Configuration bits (FWDT<3:0>), which allow the selection of 16 settings, from 1:1 to 1:32,768. Using the prescaler and postscaler time-out periods, ranges from 1 ms to 131 seconds can be achieved.

The WDT, prescaler and postscaler are reset:
• On any device Reset
• On the completion of a clock switch, whether invoked by software (i.e., setting the OSWEN bit after changing the NOSCx bits) or by hardware (i.e., Fail-Safe Clock Monitor)
• When a WFRSAV instruction is executed (i.e., Sleep or Idle mode is entered)
• When the device exits Sleep or Idle mode to resume normal operation
• By a CLRWDT instruction during normal execution

Note: The CLRWDT and WFRSAV instructions clear the prescaler and postscaler counts when executed.

27.6.2 SLEEP AND IDLE MODES

If the WDT is enabled, it continues to run during Sleep or Idle modes. When the WDT time-out occurs, the device wakes and code execution continues from where the WFRSAV instruction was executed. The corresponding SLEEP or IDLE bit (RCON<3:2>) needs to be cleared in software after the device wakes up.

27.6.3 ENABLING WDT

The WDT is enabled or disabled by the WDTEN<1:0> Configuration bits in the FWDT Configuration register. When the WDTEN<1:0> Configuration bits have been programmed to '0b11', the WDT is always enabled.

The WDT can be optionally controlled in software when the WDTEN<1:0> Configuration bits have been programmed to '0b10'. The WDT is enabled in software by setting the SWDTEn control bit (RCON<5>). The SWDTEn control bit is cleared on any device Reset. The software WDT option allows the user application to enable the WDT for critical code segments and disables the WDT during non-critical segments for maximum power savings.

The WDT Time-out flag bit, WDTO (RCON<4>), is not automatically cleared following a WDT time-out. To detect subsequent WDT events, the flag must be cleared in software.

27.6.4 WDT WINDOW

The Watchdog Timer has an optional Windowed mode, enabled by programming the WINDIS bit in the WDT Configuration register (FWDT<7>). In the Windowed mode (WINDIS = 0), the WDT should be cleared based on the settings in the programmable Watchdog Timer Window select bits (WDTWIN<1:0>).

FIGURE 27-2: WDT BLOCK DIAGRAM
27.7 JTAG Interface

The dsPIC33EPXXXGS70X/80X family devices implement a JTAG interface, which supports boundary scan device testing. Detailed information on this interface is provided in future revisions of the document.

Note: Refer to “Programming and Diagnostics” (DS70608) in the “dsPIC33/PIC24 Family Reference Manual” for further information on usage, configuration and operation of the JTAG interface.

27.8 In-Circuit Serial Programming™ (ICSP™)

The dsPIC33EPXXXGS70X/80X family devices can be serially programmed while in the end application circuit. This is done with two lines for clock and data, and three other lines for power, ground and the programming sequence. Serial programming allows customers to manufacture boards with unprogrammed devices and then program the device just before shipping the product. Serial programming also allows the most recent firmware or a custom firmware to be programmed.

Refer to the “dsPIC33E/PIC24E Flash Programming Specification for Devices with Volatile Configuration Bits” (DS70663) for details about In-Circuit Serial Programming™ (ICSP™).

Any of the three pairs of programming clock/data pins can be used:
- PGEC1 and PGED1
- PGEC2 and PGED2
- PGEC3 and PGED3

27.9 In-Circuit Debugger

When MPLAB® ICD 3 or REAL ICE™ emulator is selected as a debugger, the in-circuit debugging functionality is enabled. This function allows simple debugging functions when used with MPLAB IDE. Debugging functionality is controlled through the PGECx (Emulation/Debug Clock) and PGEDx (Emulation/Debug Data) pin functions.

Any of the three pairs of debugging clock/data pins can be used:
- PGEC1 and PGED1
- PGEC2 and PGED2
- PGEC3 and PGED3

To use the in-circuit debugger function of the device, the design must implement ICSP connections to MCLR, VDD, VSS and the PGECx/PGEDx pin pair. In addition, when the feature is enabled, some of the resources are not available for general use. These resources include the first 80 bytes of data RAM and two I/O pins (PGECx and PGEDx).

27.10 Code Protection and CodeGuard™ Security

dsPIC33EPXXXGS70X/80X devices offer multiple levels of security for protecting individual intellectual property. The program Flash protection can be broken up into three segments: Boot Segment (BS), General Segment (GS) and Configuration Segment (CS). Boot Segment has the highest security privilege and can be thought to have limited restrictions when accessing other segments. General Segment has the least security and is intended for the end user system code. Configuration Segment contains only the device user configuration data which is located at the end of the program memory space.

The code protection features are controlled by the Configuration registers, FSEC and FBSLIM. The FSEC register controls the code-protect level for each segment and if that segment is write-protected. The size of BS and GS will depend on the BSLIM<12:0> bits setting and if the Alternate Interrupt Vector Table (AIVT) is enabled. The BSLIM<12:0> bits define the number of pages for BS with each page containing 512 IW. The smallest BS size is one page, which will consist of the Interrupt Vector Table (IVT) and 256 IW of code protection.

If the AIVT is enabled, the last page of BS will contain the AIVT and will not contain any BS code. With AIVT enabled, the smallest BS size is now two pages (1024 IW), with one page for the IVT and BS code, and the other page for the AIVT. Write protection of the BS does not cover the AIVT. The last page of BS can always be programmed or erased by BS code. The General Segment will start at the next page and will consume the rest of program Flash except for the Flash Configuration Words. The IVT will assume GS security only if BS is not enabled. The IVT is protected from being programmed or page erased when either security segment has enabled write protection.

The different device security segments are shown in Figure 27-3. Here, all three segments are shown but are not required. If only basic code protection is required, then GS can be enabled independently or combined with CS, if desired.

**FIGURE 27-3: SECURITY SEGMENTS EXAMPLE FOR dsPIC33EPXXXGS70X/80X DEVICES**

<table>
<thead>
<tr>
<th>IVT and AIVT Assume BS Protection</th>
<th>GS</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x000000</td>
<td>0x000200</td>
</tr>
<tr>
<td>BS</td>

<tr>
<td>BSLIM&lt;12:0&gt;</td>
<td>0x0XXX00</td>
</tr>
<tr>
<td>CS(1)</td>
<td>0x005800</td>
</tr>
</tbody>
</table>

**Note 1:** If CS is write-protected, the last page (GS + CS) of program memory will be protected from an erase condition.

**Note 2:** The last half (256 IW) of the last page of BS is unusable program memory.

dsPIC33EPXXXGS70X/80X family devices can be operated in Dual Partition mode, where security is required for each partition. When operating in Dual Partition mode, the Active and Inactive Partitions both contain unique copies of the Reset vector, Interrupt Vector Tables (IVT and AIVT, if enabled) and the Flash Configuration Words. Both partitions have the three security segments described previously. Code may not be executed from the Inactive Partition, but it may be programmed by, and read from, the Active Partition, subject to defined code protection. Figure 27-4 and Figure 27-5 show the different security segments for devices operating in Dual Partition mode.

The device may also operate in a Protected Dual Partition mode or in Privileged Dual Partition mode. In Protected Dual Partition mode, Partition 1 is permanently erase/write-protected. This implementation allows for a "Factory Default" mode, which provides a fail-safe backup image to be stored in Partition 1. For example, a fail-safe bootloader can be placed in Partition 1, along with a fail-safe backup code image, which can be used or rewritten into Partition 2 in the event of a failed Flash update to Partition 2.

**Unimplemented (read '0's)**

**Note 1:** If CS is write-protected, the last page (GS + CS) of program memory will be protected from an erase condition.

**Note 2:** The last half (256 IW) of the last page of BS is unusable program memory.
FIGURE 27-5: SECURITY SEGMENTS
EXAMPLE FOR
dsPIC33EP128GS70X/80X
DEVICES (DUAL
PARTITION MODES)

Note 1: If CS is write-protected, the last page (GS + CS) of program memory will be protected from an erase condition.
2: The last half (256 IW) of the last page of BS is unusable program memory.
28.0 INSTRUCTION SET SUMMARY

The dsPIC33EP instruction set is almost identical to that of the dsPIC30F and dsPIC33F.

Most instructions are a single program memory word (24 bits). Only three instructions require two program memory locations.

Each single-word instruction is a 24-bit word, divided into an 8-bit opcode, which specifies the instruction type and one or more operands, which further specify the operation of the instruction.

The instruction set is highly orthogonal and is grouped into five basic categories:

- Word or byte-oriented operations
- Bit-oriented operations
- Literal operations
- DSP operations
- Control operations

Table 28-1 lists the general symbols used in describing the instructions.

The dsPIC33E instruction set summary in Table 28-2 lists all the instructions, along with the status flags affected by each instruction.

Most word or byte-oriented W register instructions (including barrel shift instructions) have three operands:

- The first source operand, which is typically a register ‘Ws’ without any address modifier
- The second source operand, which is typically a register ‘Ws’ with or without an address modifier
- The destination of the result, which is typically a register ‘Wd’ with or without an address modifier

However, word or byte-oriented file register instructions have two operands:

- The file register specified by the value ‘f’
- The destination, which could be either the file register ‘f’ or the W0 register, which is denoted as ‘WREG’

Most bit-oriented instructions (including simple rotate/shift instructions) have two operands:

- The W register (with or without an address modifier) or file register (specified by the value of ‘Ws’ or ‘f’)
- The bit in the W register or file register (specified by a literal value or indirectly by the contents of register ‘Wb’)

The literal instructions that involve data movement can use some of the following operands:

- A literal value to be loaded into a W register or file register (specified by ‘k’)
- The W register or file register where the literal value is to be loaded (specified by ‘Wb’ or ‘f’)

However, literal instructions that involve arithmetic or logical operations use some of the following operands:

- The first source operand, which is a register ‘Wb’ without any address modifier
- The second source operand, which is a literal value
- The destination of the result (only if not the same as the first source operand), which is typically a register ‘Wd’ with or without an address modifier

The MAC class of DSP instructions can use some of the following operands:

- The accumulator (A or B) to be used (required operand)
- The W registers to be used as the two operands
- The X and Y address space prefetch operations
- The X and Y address space prefetch destinations
- The accumulator write back destination

The other DSP instructions do not involve any multiplication and can include:

- The accumulator to be used (required)
- The source or destination operand (designated as Wso or Wdo, respectively) with or without an address modifier
- The amount of shift specified by a W register ‘Wn’ or a literal value

The control instructions can use some of the following operands:

- A program memory address
- The mode of the Table Read and Table Write instructions
Most instructions are a single word. Certain double-word instructions are designed to provide all the required information in these 48 bits. In the second word, the 8 MSBs are '0's. If this second word is executed as an instruction (by itself), it executes as a NOP.

The double-word instructions execute in two instruction cycles.

Most single-word instructions are executed in a single instruction cycle, unless a conditional test is true or the Program Counter is changed as a result of the instruction, or a PSV or Table Read is performed. In these cases, the execution takes multiple instruction cycles, with the additional instruction cycle(s) executed as a NOP. Certain instructions that involve skipping over the subsequent instruction require either two or three cycles if the skip is performed, depending on whether the instruction being skipped is a single-word or two-word instruction. Moreover, double-word moves require two cycles.

**Note:** For more details on the instruction set, refer to the “16-bit MCU and DSC Programmer’s Reference Manual” (DS70157).

**Note 1:** Read and Read-Modify-Write (e.g., bit operations and logical operations) on non-CPU SFRs incur an additional instruction cycle.
29.0 DEVELOPMENT SUPPORT

The PIC® microcontrollers (MCU) and dsPIC® digital signal controllers (DSC) are supported with a full range of software and hardware development tools:

- Integrated Development Environment
  - MPLAB® X IDE Software
- Compilers/Assemblers/Linkers
  - MPLAB XC Compiler
  - MPASM™ Assembler
  - MPLINK™ Object Linker/ MPLIB™ Object Librarian
  - MPLAB Assembler/Linker/Librarian for Various Device Families
- Simulators
  - MPLAB X SIM Software Simulator
- Emulators
  - MPLAB REAL ICE™ In-Circuit Emulator
- In-Circuit Debuggers/Programmers
  - MPLAB ICD 3
  - PICkit™ 3
- Device Programmers
  - MPLAB PM3 Device Programmer
- Low-Cost Demonstration/Development Boards, Evaluation Kits and Starter Kits
- Third-party development tools

29.1 MPLAB X Integrated Development Environment Software

The MPLAB X IDE is a single, unified graphical user interface for Microchip and third-party software, and hardware development tool that runs on Windows®, Linux and Mac OS® X. Based on the NetBeans IDE, MPLAB X IDE is an entirely new IDE with a host of free software components and plug-ins for high-performance application development and debugging. Moving between tools and upgrading from software simulators to hardware debugging and programming tools is simple with the seamless user interface.

With complete project management, visual call graphs, a configurable watch window and a feature-rich editor that includes code completion and context menus, MPLAB X IDE is flexible and friendly enough for new users. With the ability to support multiple tools on multiple projects with simultaneous debugging, MPLAB X IDE is also suitable for the needs of experienced users.

Feature-Rich Editor:
- Color syntax highlighting
- Smart code completion makes suggestions and provides hints as you type
- Automatic code formatting based on user-defined rules
- Live parsing

User-Friendly, Customizable Interface:
- Fully customizable interface: toolbars, toolbar buttons, windows, window placement, etc.
- Call graph window

Project-Based Workspaces:
- Multiple projects
- Multiple tools
- Multiple configurations
- Simultaneous debugging sessions

File History and Bug Tracking:
- Local file history feature
- Built-in support for Bugzilla issue tracker
29.2 MPLAB XC Compilers

The MPLAB XC Compilers are complete ANSI C compilers for all of Microchip’s 8, 16 and 32-bit MCU and DSC devices. These compilers provide powerful integration capabilities, superior code optimization and ease of use. MPLAB XC Compilers run on Windows, Linux or MAC OS X.

For easy source level debugging, the compilers provide debug information that is optimized to the MPLAB X IDE.

The free MPLAB XC Compiler editions support all devices and commands, with no time or memory restrictions, and offer sufficient code optimization for most applications.

MPLAB XC Compilers include an assembler, linker and utilities. The assembler generates relocatable object files that can then be archived or linked with other relocatable object files and archives to create an executable file. MPLAB XC Compiler uses the assembler to produce its object file. Notable features of the assembler include:

- Support for the entire device instruction set
- Support for fixed-point and floating-point data
- Command-line interface
- Rich directive set
- Flexible macro language
- MPLAB X IDE compatibility

29.3 MPASM Assembler

The MPASM Assembler is a full-featured, universal macro assembler for PIC10/12/16/18 MCUs.

The MPASM Assembler generates relocatable object files for the MPLINK Object Linker, Intel® standard HEX files, MAP files to detail memory usage and symbol reference, absolute LST files that contain source lines and generated machine code, and COFF files for debugging.

The MPASM Assembler features include:

- Integration into MPLAB X IDE projects
- User-defined macros to streamline assembly code
- Conditional assembly for multipurpose source files
- Directives that allow complete control over the assembly process

29.4 MPLINK Object Linker/ MPLIB Object Librarian

The MPLINK Object Linker combines relocatable objects created by the MPASM Assembler. It can link relocatable objects from precompiled libraries, using directives from a linker script.

The MPLIB Object Librarian manages the creation and modification of library files of precompiled code. When a routine from a library is called from a source file, only the modules that contain that routine will be linked in with the application. This allows large libraries to be used efficiently in many different applications.

The object linker/library features include:

- Efficient linking of single libraries instead of many smaller files
- Enhanced code maintainability by grouping related modules together
- Flexible creation of libraries with easy module listing, replacement, deletion and extraction

29.5 MPLAB Assembler, Linker and Librarian for Various Device Families

MPLAB Assembler produces relocatable machine code from symbolic assembly language for PIC24, PIC32 and dsPIC DSC devices. MPLAB XC Compiler uses the assembler to produce its object file. The assembler generates relocatable object files that can then be archived or linked with other relocatable object files and archives to create an executable file. Notable features of the assembler include:

- Support for the entire device instruction set
- Support for fixed-point and floating-point data
- Command-line interface
- Rich directive set
- Flexible macro language
- MPLAB X IDE compatibility
29.6 MPLAB X SIM Software Simulator

The MPLAB X SIM Software Simulator allows code development in a PC-hosted environment by simulating the PIC MCUs and dsPIC DSCs on an instruction level. On any given instruction, the data areas can be examined or modified and stimuli can be applied from a comprehensive stimulus controller. Registers can be logged to files for further run-time analysis. The trace buffer and logic analyzer display extend the power of the simulator to record and track program execution, actions on I/O, most peripherals and internal registers.

The MPLAB X SIM Software Simulator fully supports symbolic debugging using the MPLAB XC Compilers, and the MPASM and MPLAB Assemblers. The software simulator offers the flexibility to develop and debug code outside of the hardware laboratory environment, making it an excellent, economical software development tool.

29.7 MPLAB REAL ICE In-Circuit Emulator System

The MPLAB REAL ICE In-Circuit Emulator System is Microchip's next generation high-speed emulator for Microchip Flash DSC and MCU devices. It debugs and programs all 8, 16 and 32-bit MCU, and DSC devices with the easy-to-use, powerful graphical user interface of the MPLAB X IDE.

The emulator is connected to the design engineer's PC using a high-speed USB 2.0 interface and is connected to the target with either a connector compatible with in-circuit debugger systems (RJ-11) or with the new high-speed, noise tolerant, Low-Voltage Differential Signal (LVDS) interconnection (CAT5).

The emulator is field upgradable through future firmware downloads in MPLAB X IDE. MPLAB REAL ICE offers significant advantages over competitive emulators including full-speed emulation, run-time variable watches, trace analysis, complex breakpoints, logic probes, a ruggedized probe interface and long (up to three meters) interconnection cables.

29.8 MPLAB ICD 3 In-Circuit Debugger System

The MPLAB ICD 3 In-Circuit Debugger System is Microchip's most cost-effective, high-speed hardware debugger/programmer for Microchip Flash DSC and MCU devices. It debugs and programs PIC Flash microcontrollers and dsPIC DSCs with the powerful, yet easy-to-use graphical user interface of the MPLAB IDE.

The MPLAB ICD 3 In-Circuit Debugger probe is connected to the design engineer's PC using a high-speed USB 2.0 interface and is connected to the target with a connector compatible with the MPLAB ICD 2 or MPLAB REAL ICE systems (RJ-11). MPLAB ICD 3 supports all MPLAB ICD 2 headers.

29.9 PICkit 3 In-Circuit Debugger/Programmer

The MPLAB PICkit 3 allows debugging and programming of PIC and dsPIC Flash microcontrollers at a most affordable price point using the powerful graphical user interface of the MPLAB IDE. The MPLAB PICkit 3 is connected to the design engineer's PC using a full-speed USB interface and can be connected to the target via a Microchip debug (RJ-11) connector (compatible with MPLAB ICD 3 and MPLAB REAL ICE). The connector uses two device I/O pins and the Reset line to implement in-circuit debugging and In-Circuit Serial Programming™ (ICSP™).

29.10 MPLAB PM3 Device Programmer

The MPLAB PM3 Device Programmer is a universal, CE compliant device programmer with programmable voltage verification at VDDMIN and VDDMAX for maximum reliability. It features a large LCD display (128 x 64) for menus and error messages, and a modular, detachable socket assembly to support various package types. The ICSP cable assembly is included as a standard item. In Stand-Alone mode, the MPLAB PM3 Device Programmer can read, verify and program PIC devices without a PC connection. It can also set code protection in this mode. The MPLAB PM3 connects to the host PC via an RS-232 or USB cable. The MPLAB PM3 has high-speed communications and optimized algorithms for quick programming of large memory devices, and incorporates an MMC card for file storage and data applications.
29.11 Demonstration/Development Boards, Evaluation Kits and Starter Kits

A wide variety of demonstration, development and evaluation boards for various PIC MCUs and dsPIC DSCs allows quick application development on fully functional systems. Most boards include prototyping areas for adding custom circuitry and provide application firmware and source code for examination and modification.

The boards support a variety of features, including LEDs, temperature sensors, switches, speakers, RS-232 interfaces, LCD displays, potentiometers and additional EEPROM memory.

The demonstration and development boards can be used in teaching environments, for prototyping custom circuits and for learning about various microcontroller applications.

In addition to the PICDEM™ and dsPICDEM™ demonstration/development board series of circuits, Microchip has a line of evaluation kits and demonstration software for analog filter design, Keeloq® security ICs, CAN, IrDA®, PowerSmart battery management, SEEVAL® evaluation system, Sigma-Delta ADC, flow rate sensing, plus many more.

Also available are starter kits that contain everything needed to experience the specified device. This usually includes a single application and debug capability, all on one board.

Check the Microchip web page (www.microchip.com) for the complete list of demonstration, development and evaluation kits.

29.12 Third-Party Development Tools

Microchip also offers a great collection of tools from third-party vendors. These tools are carefully selected to offer good value and unique functionality.

- Device Programmers and Gang Programmers from companies, such as SoftLog and CCS
- Software Tools from companies, such as Gimpel and Trace Systems
- Protocol Analyzers from companies, such as Saleae and Total Phase
- Demonstration Boards from companies, such as MikroElektronika, Digilent® and Olimex
- Embedded Ethernet Solutions from companies, such as EZ Web Lynx, WIZnet and IPLogika®
30.0 ELECTRICAL CHARACTERISTICS

This section provides an overview of the dsPIC33EPXXXGS70X/80X family electrical characteristics. Additional information will be provided in future revisions of this document as it becomes available.

Absolute maximum ratings for the dsPIC33EPXXXGS70X/80X family are listed below. Exposure to these maximum rating conditions for extended periods may affect device reliability. Functional operation of the device at these, or any other conditions above the parameters indicated in the operation listings of this specification, is not implied.

**Absolute Maximum Ratings**

<table>
<thead>
<tr>
<th>Condition</th>
<th>Specification</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ambient temperature under bias</td>
<td>-40°C to +125°C</td>
</tr>
<tr>
<td>Storage temperature</td>
<td>-65°C to +150°C</td>
</tr>
<tr>
<td>Voltage on VDD with respect to VSS</td>
<td>-0.3V to +4.0V</td>
</tr>
<tr>
<td>Voltage on any pin that is not 5V tolerant with respect to VSS</td>
<td>-0.3V to (VDD + 0.3V)</td>
</tr>
<tr>
<td>Voltage on any 5V tolerant pin with respect to VSS when VDD ( \geq ) 3.0V</td>
<td>-0.3V to +5.5V</td>
</tr>
<tr>
<td>Voltage on any 5V tolerant pin with respect to VSS when VDD &lt; 3.0V</td>
<td>-0.3V to +3.6V</td>
</tr>
<tr>
<td>Maximum current out of VSS pin</td>
<td>300 mA</td>
</tr>
<tr>
<td>Maximum current into VDD pin</td>
<td>300 mA</td>
</tr>
<tr>
<td>Maximum current sunk/sourced by any 4x I/O pin</td>
<td>15 mA</td>
</tr>
<tr>
<td>Maximum current sunk/sourced by any 8x I/O pin</td>
<td>25 mA</td>
</tr>
<tr>
<td>Maximum current sunk by all ports</td>
<td>200 mA</td>
</tr>
</tbody>
</table>

**Note 1:** Stresses above those listed under “Absolute Maximum Ratings” may cause permanent damage to the device. This is a stress rating only and functional operation of the device at those, or any other conditions above those indicated in the operation listings of this specification, is not implied. Exposure to maximum rating conditions for extended periods may affect device reliability.

2: Maximum allowable current is a function of device maximum power dissipation (see Table 30-2).

3: See the “Pin Diagrams” section for the 5V tolerant pins.
### 30.1 DC Characteristics

**TABLE 30-1: OPERATING MIPS vs. VOLTAGE**

<table>
<thead>
<tr>
<th>Characteristic</th>
<th>VDD Range (in Volts)</th>
<th>Temperature Range (in °C)</th>
<th>Maximum MIPS</th>
</tr>
</thead>
<tbody>
<tr>

<td>+85°C</td>
</tr>
</tbody>
</table>

Note 1: IDD is primarily a function of the operating voltage and frequency. Other factors, such as I/O pin loading and switching rate, oscillator type, internal code execution pattern and temperature, also have an impact on the current consumption. The test conditions for all IDD measurements are as follows:
- Oscillator is configured in EC mode with PLL, OSC1 is driven with external square wave from rail-to-rail (EC clock overshoot/undershoot < 250 mV required)
- CLKO is configured as an I/O input pin in the Configuration Word
- All I/O pins are configured as inputs and pulled to Vss
- MCLR = Vdd, WDT and FSCM are disabled
- CPU, SRAM, program memory and data memory are operational
- No peripheral modules are operating or being clocked (all defined PMDx bits are set)
- CPU is executing while(1) statement
- JTAG is disabled

Note 2: For this specification, the following test conditions apply:
- APLL clock is enabled
- All 8 PWMs enabled and operating at maximum speed (PTCON2<2:0> = 000), PTPER = 1000h, 50% duty cycle
- All other peripherals are disabled (corresponding PMDx bits are set)

**Note 1:** Base Idle current (I\_IDLE) is measured as follows:
- CPU core is off, oscillator is configured in EC mode and external clock is active; OSC1 is driven with external square wave from rail-to-rail (EC clock overshoot/undershoot < 250 mV required)
- CLKO is configured as an I/O input pin in the Configuration Word
- All I/O pins are configured as inputs and pulled to VSS
- MCLR = VDD, WDT and FSCM are disabled
- No peripheral modules are operating or being clocked (all defined PMDx bits are set)
- The NVMSIDL bit (NVMCON<12>) = 1 (i.e., Flash regulator is set to standby while the device is in Idle mode)
- The VREGSF bit (RCON<11>) = 0 (i.e., Flash regulator is set to standby while the device is in Sleep mode)
- JTAG is disabled

</tr>
</tbody>
</table>

Note 1: IDOZE is primarily a function of the operating voltage and frequency. Other factors, such as I/O pin loading and switching rate, oscillator type, internal code execution pattern and temperature, also have an impact on the current consumption. The test conditions for all IDOZE measurements are as follows:
- Oscillator is configured in EC mode and external clock is active, OSC1 is driven with external square wave from rail-to-rail (EC clock overshoot/undershoot < 250 mV required)
- CLKO is configured as an I/O input pin in the Configuration Word
- All I/O pins are configured as inputs and pulled to VSS
- MCLR = VDD, WDT and FSCM are disabled
- CPU, SRAM, program memory and data memory are operational
- No peripheral modules are operating or being clocked (all defined PMDx bits are set)
- CPU is executing while(1) statement
- JTAG is disabled

2: These parameter are characterized but not tested in manufacturing.

</tbody>
</table>

**Note:**
1: Data in “Typ.” column is at 3.3V, +25°C unless otherwise stated.
2: The leakage current on the MCLR pin is strongly dependent on the applied voltage level. The specified levels represent normal operating conditions. Higher leakage current can be measured at different input voltages.
3: Negative current is defined as current sourced by the pin.
4: See the “Pin Diagrams” section for the 5V tolerant I/O pins.
5: VIL Source < (VSS – 0.3). Characterized but not tested.
6: VIH Source > (VDD + 0.3) for pins that are not 5V tolerant only.
7: Digital 5V tolerant pins do not have internal high-side diodes to VDD and cannot tolerate any “positive” input injection current.
8: Injection Currents > | 0 | can affect the ADC results by approximately 4-6 counts.
9: Any number and/or combination of I/O pins not excluded under IICL or IICH conditions are permitted provided the mathematical “absolute instantaneous” sum of the input injection currents from all pins do not exceed the specified limit. Characterized but not tested.

</tbody>
</table>

**Note 1:** Data in “Typ.” column is at 3.3V, +25°C unless otherwise stated.

**Note 2:** Parameter characterized but not tested in manufacturing.

**Note 3:** Other conditions: FRC = 7.37 MHz, TUN<5:0> = 011111 (for Minimum), TUN<5:0> = 100000 (for Maximum). This parameter depends on the FRC accuracy (see Table 30-20) and the value of the FRC Oscillator Tuning register (see Register 9-4). For complete details on calculating the Minimum and Maximum time, see Section 5.3 “Programming Operations”.

</tbody>
</table>

**Note:**
1. Data in “Typ.” column is at 3.3V, +25°C unless otherwise stated.
2. Instruction cycle period (TCy) equals two times the input oscillator time base period. All specified values are based on characterization data for that particular oscillator type, under standard operating conditions, with the device executing code. Exceeding these specified limits may result in an unstable oscillator operation and/or higher than expected current consumption. All devices are tested to operate at “Minimum” values with an external clock applied to the OSC1 pin. When an external clock input is used, the “Maximum” cycle time limit is “DC” (no clock) for all devices.
3. Measurements are taken in EC mode. The CLKO signal is measured on the OSC2 pin.
4. This parameter is characterized but not tested in manufacturing.

**Note 1:** Data in “Typ.” column is at 3.3V, +25°C unless otherwise stated. Parameters are for design guidance only and are not tested.

2: This jitter specification is based on clock cycle-by-clock cycle measurements. To get the effective jitter for individual time bases, or communication clocks used by the application, use the following formula:

\[
\text{Effective Jitter} = \frac{D_{CLK}}{\sqrt{\frac{\text{FOSC}}{\text{Time Base or Communication Clock}}}}
\]

For example, if Fosc = 120 MHz and the SPIx bit rate = 10 MHz, the effective jitter is as follows:

\[
\text{Effective Jitter} = \frac{D_{CLK}}{\sqrt{\frac{120}{10}}} = \frac{D_{CLK}}{\sqrt{12}} = \frac{D_{CLK}}{3.464}
\]

APPENDIX A: REVISION HISTORY

Revision A (May 2016)
This is the initial version of the document.

Revision B (January 2017)

- Sections:
  - Updates Note 1 in Section 5.0 “Flash Program Memory”.

- Tables:
  - Updates the device description table on page 2.
  - Updates Table 1-1, Table 4-2, Table 4-11, Table 7-1, Table 8-1, Table 11-11, Table 11-13, Table 17-1, Table 30-3, Table 30-4, Table 30-6, Table 30-7, Table 30-8, Table 30-9, Table 30-10, Table 30-11, Table 30-52, Table 30-54 and Table 30-55.
  - Adds Table 11-6, Table 11-7, Table 11-8, Table 11-9 and Table 11-10.

- Figures:
  - Updates the Pin Function tables in the Pin Diagram figures on pages 5 through 8.
  - Updates Figure 4-1, Figure 17-1, Figure 18-1 and Figure 18-2.

- Registers:
  - Updates Register 3-3, Register 16-5, Register 17-11, Register 18-1 and Register 19-2.
  - Adds Register 11-1, Register 11-2, Register 11-3, Register 11-4, Register 11-5, Register 11-6, Register 11-7 and Register 11-8.

THE MICROCHIP WEB SITE

Microchip provides online support via our WWW site at www.microchip.com. This web site is used as a means to make files and information easily available to customers. Accessible by using your favorite Internet browser, the web site contains the following information:

• **Product Support** – Data sheets and errata, application notes and sample programs, design resources, user’s guides and hardware support documents, latest software releases and archived software
• **General Technical Support** – Frequently Asked Questions (FAQ), technical support requests, online discussion groups, Microchip consultant program member listing
• **Business of Microchip** – Product selector and ordering guides, latest Microchip press releases, listing of seminars and events, listings of Microchip sales offices, distributors and factory representatives

CUSTOMER CHANGE NOTIFICATION SERVICE

Microchip’s customer notification service helps keep customers current on Microchip products. Subscribers will receive e-mail notification whenever there are changes, updates, revisions or errata related to a specified product family or development tool of interest.

To register, access the Microchip web site at www.microchip.com. Under “Support”, click on “Customer Change Notification” and follow the registration instructions.

CUSTOMER SUPPORT

Users of Microchip products can receive assistance through several channels:

• Distributor or Representative
• Local Sales Office
• Field Application Engineer (FAE)
• Technical Support

Customers should contact their distributor, representative or Field Application Engineer (FAE) for support. Local sales offices are also available to help customers. A listing of sales offices and locations is included in the back of this document.

Technical support is available through the web site at: http://microchip.com/support
## PRODUCT IDENTIFICATION SYSTEM

To order or obtain information, e.g., on pricing or delivery, refer to the factory or the listed sales office.

### Examples:

| dsPIC33EP64GS804-I/PT: | dsPIC33, Enhanced Performance, 64-Kbyte Program Memory, SMPS, 44-Pin, Industrial Temperature, TQFP Package. |

Note the following details of the code protection feature on Microchip devices:

• Microchip products meet the specification contained in their particular Microchip Data Sheet.

• Microchip believes that its family of products is one of the most secure families of its kind on the market today, when used in the intended manner and under normal conditions.

• There are dishonest and possibly illegal methods used to breach the code protection feature. All of these methods, to our knowledge, require using the Microchip products in a manner outside the operating specifications contained in Microchip’s Data Sheets. Most likely, the person doing so is engaged in theft of intellectual property.

• Microchip is willing to work with the customer who is concerned about the integrity of their code.

• Neither Microchip nor any other semiconductor manufacturer can guarantee the security of their code. Code protection does not mean that we are guaranteeing the product as “unbreakable.”

Code protection is constantly evolving. We at Microchip are committed to continuously improving the code protection features of our products. Attempts to break Microchip’s code protection feature may be a violation of the Digital Millennium Copyright Act. If such acts allow unauthorized access to your software or other copyrighted work, you may have a right to sue for relief under that Act.

Information contained in this publication regarding device applications and the like is provided only for your convenience and may be superseded by updates. It is your responsibility to ensure that your application meets with your specifications. MICROCHIP MAKES NO REPRESENTATIONS OR WARRANTIES OF ANY KIND WHETHER EXPRESS OR IMPLIED, WRITTEN OR ORAL, STATUTORY OR OTHERWISE, RELATED TO THE INFORMATION, INCLUDING BUT NOT LIMITED TO ITS CONDITION, QUALITY, PERFORMANCE, MERCHANTABILITY OR FITNESS FOR PURPOSE. Microchip disclaims all liability arising from this information and its use. Use of Microchip devices in life support and/or safety applications is entirely at the buyer’s risk, and the buyer agrees to defend, indemnify and hold harmless Microchip from any and all damages, claims, suits, or expenses resulting from such use. No licenses are conveyed, implicitly or otherwise, under any Microchip intellectual property rights unless otherwise stated.

Microchip received ISO/TS-16949:2009 certification for its worldwide headquarters, design and wafer fabrication facilities in Chandler and Tempe, Arizona; Gresham, Oregon and design centers in California and India. The Company’s quality system processes and procedures are for its PIC® MCUs and dsPIC® DSCs, KEELOQ® code hopping devices, Serial EEPROMs, microperipherals, nonvolatile memory and analog products. In addition, Microchip’s quality system for the design and manufacture of development systems is ISO 9001:2000 certified.
