Section 6. Interrupts

HIGHLIGHTS

This section of the manual contains the following topics:

6.1 Introduction ........................................................................................................... 6-2
6.2 Non-Maskable Traps .............................................................................................. 6-6
6.3 Interrupt Processing Timing .................................................................................. 6-11
6.4 Interrupt Control and Status Registers ................................................................. 6-14
6.5 Interrupt Setup Procedures .................................................................................... 6-42
6.6 Register Map ......................................................................................................... 6-43
6.7 Design Tips ............................................................................................................ 6-44
6.8 Related Application Notes ..................................................................................... 6-45
6.9 Revision History ................................................................................................... 6-46
6.1 Introduction

The dsPIC30F interrupt controller module reduces the numerous peripheral interrupt request signals to a single interrupt request signal to the dsPIC30F CPU and has the following features:

- Up to 8 processor exceptions and software traps
- 7 user selectable priority levels
- Interrupt Vector Table (IVT) with up to 62 vectors
- A unique vector for each interrupt or exception source
- Fixed priority within a specified user priority level
- Alternate Interrupt Vector Table (AIVT) for debug support
- Fixed interrupt entry and return latencies

6.1.1 Interrupt Vector Table

The Interrupt Vector Table (IVT) is shown in Figure 6-1. The IVT resides in program memory, starting at location \(0x000004\). The IVT contains 62 vectors consisting of 8 non-maskable trap vectors plus up to 54 sources of interrupt. In general, each interrupt source has its own vector. Each interrupt vector contains a 24-bit wide address. The value programmed into each interrupt vector location is the starting address of the associated Interrupt Service Routine (ISR).

6.1.2 Alternate Vector Table

The Alternate Interrupt Vector Table (AIVT) is located after the IVT as shown in Figure 6-1. Access to the AIVT is provided by the ALTIVT control bit (INTCON2<15>). If the ALTIVT bit is set, all interrupt and exception processes will use the alternate vectors instead of the default vectors. The alternate vectors are organized in the same manner as the default vectors.

The AIVT supports emulation and debugging efforts by providing a means to switch between an application and a support environment without requiring the interrupt vectors to be reprogrammed. This feature also enables switching between applications for evaluation of different software algorithms at run-time. If the AIVT is not needed, the AIVT should be programmed with the same addresses used in the IVT.

6.1.3 Reset Sequence

A device Reset is not a true exception because the interrupt controller is not involved in the Reset process. The dsPIC30F device clears its registers in response to a Reset which forces the PC to zero. The processor then begins program execution at location \(0x000000\). The user programs a GOTO instruction at the Reset address which redirects program execution to the appropriate start-up routine.

**Note:** Any unimplemented or unused vector locations in the IVT and AIVT should be programmed with the address of a default interrupt handler routine that contains a RESET instruction.

## 6.1.4 CPU Priority Status

The CPU can operate at one of six priority levels, 0-15. An interrupt or trap source must have a priority level greater than the current CPU priority in order to initiate an exception process. Peripheral and external interrupt sources can be programmed for level 0-7, while CPU priority levels 8-15 are reserved for trap sources. A trap is a non-maskable interrupt source intended to detect hardware and software problems (see Section 6.2 “Non-Maskable Traps”). The priority level for each trap source is fixed and only one trap is assigned to a priority level. Note that an interrupt source programmed to priority level 0 is effectively disabled, since it can never be greater than the CPU priority.

The current CPU priority level is indicated by the following four status bits:

- IPL<2:0> status bits located in SR<7:5>
- IPL3 status bit located in CORCON<3>

The IPL<2:0> status bits are readable and writable, so the user may modify these bits to disable all sources of interrupts below a given priority level. If IPL<2:0> = 3, for example, the CPU will not be interrupted by any source with a programmed priority level of 0, 1, 2 or 3.

Trap events have higher priority than any user interrupt source. When the IPL3 bit is set, a trap event is in progress. The IPL3 bit can be cleared, but not set by the user. In some applications, it may be desirable to clear the IPL3 bit when a trap has occurred and branch to an instruction other than the instruction after the one that originally caused the trap to occur.

All user interrupt sources can be disabled by setting IPL<2:0> = 111.

### Note:
The IPL<2:0> bits become read only bits when interrupt nesting is disabled. See Section 6.2.4.2 “Interrupt Nesting” for more information.

## 6.1.5 Interrupt Priority

Each peripheral interrupt source can be assigned to one of the seven priority levels. The user assignable interrupt priority control bits for each individual interrupt are located in the Least Significant 3 bits of each nibble within the IPCx register(s). Bit 3 of each nibble is not used and is read as a ‘0’. These bits define the priority level assigned to a particular interrupt. The usable priority levels start at ‘1’ as the lowest priority and level 7 as the highest priority. If the IPC bits associated with an interrupt source are all cleared, then the interrupt source is effectively disabled.

### Note:
If the application program reconfigures the interrupt priority levels on the fly, it must disable the interrupts while doing so. Failure to disable interrupts can produce unexpected results.

Since more than one interrupt request source may be assigned to a specific priority level, an option is provided to resolve priority conflicts within a given user-assigned level. Each source of interrupt has a natural order priority based on its location in the IVT. Table 6-2 shows the location of each interrupt source in the IVT. The lower numbered interrupt vectors have higher natural priority, while the higher numbered vectors have lower natural priority. The overall priority level for any pending source of interrupt is determined first by the user-assigned priority of that source in the IPCx register, then by the natural order priority within the IVT.

Natural order priority is used only to resolve conflicts between simultaneous pending interrupts with the same user-assigned priority level. Once the priority conflict is resolved and the exception process begins, the CPU can only be interrupted by a source with a higher user-assigned priority. Interrupts with the same user-assigned priority but a higher natural order priority, that become pending after the exception process begins, will remain pending until the current exception process completes.

The ability for the user to assign each interrupt source to one of seven priority levels means that the user can give an interrupt with a low natural order priority a very high overall priority level. For example: the PLVD (Programmable Low Voltage Detect) can be given a priority of 7 and the INT0 (External Interrupt 0) may be assigned to priority level 1, thus giving it a very low effective priority.

### Note:
The peripherals and sources of interrupt available in the IVT will vary depending on the specific dsPIC30F device. The sources of interrupt shown in this document represent a comprehensive listing of all interrupt sources found on dsPIC30F devices. Refer to the specific device data sheet for further details.
6.2 Non-Maskable Traps

Traps can be considered as non-maskable, nestable interrupts which adhere to a fixed priority structure. Traps are intended to provide the user a means to correct erroneous operation during debug and when operating within the application. If the user does not intend to take corrective action in the event of a trap error condition, these vectors must be loaded with the address of a software routine that will reset the device. Otherwise, the trap vector is programmed with the address of a service routine that will correct the trap condition.

The dsPIC30F has the four implemented sources of non-maskable traps listed below:

- Oscillator Failure Trap
- Stack Error Trap
- Address Error Trap
- Arithmetic Error Trap

Note that many of these trap conditions can only be detected when they happen. Consequently, the instruction that caused the trap is allowed to complete before exception processing begins. Therefore, the user may have to correct the action of the instruction that caused the trap.

Each trap source has a fixed priority as defined by its position in the IVT. An oscillator failure trap has the highest priority, while an arithmetic error trap has the lowest priority (see Figure 6-1). In addition, trap sources are classified into two distinct categories: ‘Hard’ traps and ‘Soft’ traps.

6.2.1 Soft Traps

The arithmetic error trap (priority level 11) and stack error trap (priority level 12) are categorized as ‘soft’ trap sources. Soft traps can be treated like non-maskable sources of interrupt that adhere to the priority assigned by their position in the IVT. Soft traps are processed like interrupts and require 2 cycles to be sampled and Acknowledged prior to exception processing. Therefore, additional instructions may be executed before a soft trap is Acknowledged.

6.2.1.1 Stack Error Trap (Soft Trap, Level 12)

The stack is initialized to 0x0800 during Reset. A stack error trap will be generated should the stack pointer address ever be less than 0x0800.

There is a Stack Limit register (SPLIM) associated with the stack pointer that is uninitialized at Reset. The stack overflow check is not enabled until a word write to SPLIM occurs. All Effective Addresses (EA) generated using W15 as a source or destination pointer are compared against the value in SPLIM. Should the EA be greater than the contents of the SPLIM register, then a stack error trap is generated. In addition, a stack error trap will be generated should the EA calculation wrap over the end of data space (0xFFFF).

A stack error can be detected in software by polling the STKERR status bit (INTCON1<2>). To avoid re-entering the Trap Service Routine, the STKERR status flag must be cleared in software prior to returning from the trap with a RETFIE instruction.
6.2.1.2 Arithmetic Error Trap (Soft Trap, Level 11)

Any of the following events will cause an arithmetic error trap to be generated:

- Accumulator A Overflow
- Accumulator B Overflow
- Catastrophic Accumulator Overflow
- Divide by Zero
- Shift Accumulator (SFTAC) operation exceeding +/-16 bits

There are three enable bits in the INTCON1 register that enable the three types of accumulator overflow traps. The OVATE control bit (INTCON1<10>) is used to enable traps for an Accumulator A overflow event. The OVBTE control bit (INTCON1<9>) is used to enable traps for an Accumulator B overflow event. The COVTE control bit (INTCON1<8>) is used to enable traps for a catastrophic overflow of either accumulator.

An Accumulator A or Accumulator B overflow event is defined as a carry-out from bit 31. Note that no accumulator overflow can occur if the 31-bit Saturation mode is enabled for the accumulator. A catastrophic accumulator overflow is defined as a carry-out from bit 39 of either accumulator. No catastrophic overflow can occur if accumulator saturation (31-bit or 39-bit) is enabled.

Divide-by-zero traps cannot be disabled. The divide-by-zero check is performed during the first iteration of the REPEAT loop that executes the divide instruction.

Accumulator shift traps cannot be disabled. The SFTAC instruction can be used to shift the accumulator by a literal value or a value in one of the W registers. If the shift value exceeds +/-16 bits, an arithmetic trap will be generated. The SFTAC instruction will execute, but the results of the shift will not be written to the target accumulator.

An arithmetic error trap can be detected in software by polling the MATHERR status bit (INTCON1<4>). To avoid re-entering the Trap Service Routine, the MATHERR status flag must be cleared in software prior to returning from the trap with a RETFIE instruction. Before the MATHERR status bit can be cleared, all conditions that caused the trap to occur must also be cleared. If the trap was due to an accumulator overflow, the OA and OB status bits (SR<15:14>) must be cleared. The OA and OB status bits are read only, so the user software must perform a dummy operation on the overflowed accumulator (such as adding ‘0’) that will cause the hardware to clear the OA or OB status bit.

6.2.2 Hard Traps

Hard traps include exceptions of priority level 13 through level 15, inclusive. The address error (level 13) and oscillator error (level 14) traps fall into this category.

Like soft traps, hard traps can also be viewed as non-maskable sources of interrupt. The difference between hard traps and soft traps is that hard traps force the CPU to stop code execution after the instruction causing the trap has completed. Normal program execution flow will not resume until after the trap has been Acknowledged and processed.

6.2.2.1 Trap Priority and Hard Trap Conflicts

If a higher priority trap occurs while any lower priority trap is in progress, processing of the lower priority trap will be suspended and the higher priority trap will be Acknowledged and processed. The lower priority trap will remain pending until processing of the higher priority trap completes.

Each hard trap that occurs must be Acknowledged before code execution of any type may continue. If a lower priority hard trap occurs while a higher priority trap is pending, Acknowledged, or is being processed, a hard trap conflict will occur. The conflict occurs because the lower priority trap cannot be Acknowledged until processing for the higher priority trap completes.

The device is automatically reset in a hard trap conflict condition. The TRAPR status bit (RCON<15>) is set when the Reset occurs, so that the condition may be detected in software.
6.2.2 Oscillator Failure Trap (Hard Trap, Level 14)

An oscillator failure trap event will be generated for any of the following reasons:

- The Fail-Safe Clock Monitor (FSCM) is enabled and has detected a loss of the system clock source.
- A loss of PLL lock has been detected during normal operation using the PLL.
- The FSCM is enabled and the PLL fails to achieve lock at a Power-On Reset (POR).

An oscillator failure trap event can be detected in software by polling the OSCFAIL status bit (INTCON1<1>), or the CF status bit (OSCCON<3>). To avoid re-entering the Trap Service Routine, the OSCFAIL status flag must be cleared in software prior to returning from the trap with a RETFIE instruction.

For more information about the FSCM, refer to Section 7. “Oscillator” and Section 24. “Device Configuration”.

6.2.2.3 Address Error Trap (Hard Trap, Level 13)

The following paragraphs describe operating scenarios that would cause an address error trap to be generated:

1. A misaligned data word fetch is attempted. This condition occurs when an instruction performs a word access with the LSb of the effective address set to ‘1’. The dsPIC30F CPU requires all word accesses to be aligned to an even address boundary.
2. A bit manipulation instruction using the Indirect Addressing mode with the LSb of the effective address set to ‘1’.
3. A data fetch from unimplemented data address space is attempted.
4. Execution of a "BRA #literal" instruction or a "GOTO #literal" instruction, where literal is an unimplemented program memory address.
5. Executing instructions after modifying the PC to point to unimplemented program memory addresses. The PC may be modified by loading a value into the stack and executing a RETURN instruction.

Data space writes will be inhibited whenever an address error trap occurs, so that data is not destroyed.

An address error can be detected in software by polling the ADDERR status bit (INTCON1<3>). To avoid re-entering the Trap Service Routine, the ADDERR status flag must be cleared in software prior to returning from the trap with a RETFIE instruction.

Note: In the MAC class of instructions, the data space is split into X and Y spaces. In these instructions, unimplemented X space includes all of Y space, and unimplemented Y space includes all of X space.

6.2.3 Disable Interrupts Instruction

The DISI (disable interrupts) instruction has the ability to disable interrupts for up to 16384 instruction cycles. This instruction is useful when time critical code segments must be executed.

The DISI instruction only disables interrupts with priority levels 1-6. Priority level 7 interrupts and all trap events still have the ability to interrupt the CPU when the DISI instruction is active.

The DISI instruction works in conjunction with the DISICNT register. When the DISICNT register is non-zero, priority level 1-6 interrupts are disabled. The DISICNT register is decremented on each subsequent instruction cycle. When the DISICNT register counts down to ‘0’, priority level 1-6 interrupts will be re-enabled. The value specified in the DISI instruction includes all cycles due to PSV accesses, instruction stalls, etc.

The DISICNT register is readable and writable. The user can terminate the effect of a previous DISI instruction early by clearing the DISICNT register. The amount of time that interrupts are disabled can also be increased by writing to or adding to DISICNT.
Section 6. Interrupts

Note that if the DISICNT register is zero, interrupts cannot be disabled by writing a non-zero value to the register. Interrupts must first be disabled by using the DISI instruction. Once the DISI instruction has executed and DISICNT holds a non-zero value, the interrupt disable time can be extended by modifying the contents of DISICNT.

Note: Software modification of the DISICNT register is not recommended.

The DISI status bit (INTCON2<14>) is set whenever interrupts are disabled as a result of the DISI instruction.

Note: The DISI instruction can be used to quickly disable all user interrupt sources if no source is assigned to CPU priority level 7.

6.2.4 Interrupt Operation

All interrupt event flags are sampled during each instruction cycle. A pending Interrupt Request (IRQ) is indicated by the flag bit being equal to a ‘1’ in an IFSx register. The IRQ will cause an interrupt to occur if the corresponding bit in the Interrupt Enable (IECx) registers is set. For the rest of the instruction cycle in which the IRQ is sampled, the priorities of all pending interrupt requests are evaluated.

No instruction will be aborted when the CPU responds to the IRQ. The instruction that was in progress when the IRQ is sampled will be completed before the ISR is executed.

If there is a pending IRQ with a user-assigned priority level greater than the current processor priority level, indicated by the IPL<2:0> status bits (SR<7:5>), an interrupt will be presented to the processor. The processor then saves the following information on the software stack:

• the current PC value
• the low byte of the Processor Status register (SRL)
• the IPL3 status bit (CORCON<3>)

These three values that are saved on the stack allow the return PC address value, MCU status bits, and the current processor priority level to be automatically saved.

After the above information is saved on the stack, the CPU writes the priority level of the pending interrupt into the IPL<2:0> bit locations. This action will disable all interrupts of less than, or equal priority, until the Interrupt Service Routine (ISR) is terminated using the RETFIE instruction.

Figure 6-2: Stack Operation for Interrupt Event

6.2.4.1 Return from Interrupt

The RETFIE (Return from Interrupt) instruction will unstack the PC return address, IPL3 status bit and SRL register to return the processor to the state and priority level prior to the interrupt sequence.
6.2.4.2 Interrupt Nesting

Interrupts, by default, are nestable. Any ISR that is in progress may be interrupted by another source of interrupt with a higher user-assigned priority level. Interrupt nesting may be optionally disabled by setting the NSTDIS control bit (INTCON1<15>). When the NSTDIS control bit is set, all interrupts in progress will force the CPU priority to level 7 by setting IPL<2:0> = 111. This action will effectively mask all other sources of interrupt until a RETFIE instruction is executed. When interrupt nesting is disabled, the user-assigned interrupt priority levels will have no effect, except to resolve conflicts between simultaneous pending interrupts.

The IPL<2:0> bits become read only when interrupt nesting is disabled. This prevents the user software from setting IPL<2:0> to a lower value, which would effectively re-enable interrupt nesting.

6.2.5 Wake-up from Sleep and Idle

Any source of interrupt that is individually enabled, using its corresponding control bit in the IECx registers, can wake-up the processor from Sleep or Idle mode. When the interrupt status flag for a source is set and the interrupt source is enabled via the corresponding bit in the IEC Control registers, a wake-up signal is sent to the dsPIC30F CPU. When the device wakes from Sleep or Idle mode, one of the following actions may occur:

1. If the interrupt priority level for that source is greater than the current CPU priority level, then the processor will process the interrupt and branch to the ISR for the interrupt source.
2. If the user-assigned interrupt priority level for the source is less than or equal the current CPU priority level, then the processor will simply continue execution, starting with the instruction immediately following the PWRSAV instruction that previously put the CPU in Sleep or Idle mode.

**Note:** User interrupt sources that are assigned to CPU priority level 0 cannot wake the CPU from Sleep or Idle mode, because the interrupt source is effectively disabled. To use an interrupt as a wake-up source, the CPU priority level for the interrupt must be assigned to CPU priority level 1 or greater.

6.2.6 A/D Converter External Conversion Request

The INT0 external interrupt request pin is shared with the A/D converter as an external conversion request signal. The INT0 interrupt source has programmable edge polarity, which is also available to the A/D converter external conversion request feature.

6.2.7 External Interrupt Support

The dsPIC30F supports up to 5 external interrupt pin sources (INT0-INT4). Each external interrupt pin has edge detection circuitry to detect the interrupt event. The INTCON2 register has five control bits (INT0EP-INT4EP) that select the polarity of the edge detection circuitry. Each external interrupt pin may be programmed to interrupt the CPU on a rising edge or falling edge event. See Register 6-4 for further details.
6.3 Interrupt Processing Timing

6.3.1 Interrupt Latency for One-Cycle Instructions

Figure 6-3 shows the sequence of events when a peripheral interrupt is asserted during a one-cycle instruction. The interrupt process takes four instruction cycles. Each cycle is numbered in the Figure for reference.

The interrupt flag status bit is set during the instruction cycle after the peripheral interrupt occurs. The current instruction completes during this instruction cycle. In the second instruction cycle after the interrupt event, the contents of the PC and SRL registers are saved into a temporary buffer register. The second cycle of the interrupt process is executed as a \texttt{NOP} to maintain consistency with the sequence taken during a two-cycle instruction (see Section 6.3.2 “Interrupt Latency for Two-Cycle Instructions”). In the third cycle, the PC is loaded with the vector table address for the interrupt source and the starting address of the ISR is fetched. In the fourth cycle, the PC is loaded with the ISR address. The fourth cycle is executed as a \texttt{NOP} while the first instruction in the ISR is fetched.

Figure 6-3: Interrupt Timing During a One-Cycle Instruction
6.3.2 Interrupt Latency for Two-Cycle Instructions

The interrupt latency during a two-cycle instruction is the same as during a one-cycle instruction. The first and second cycle of the interrupt process allow the two-cycle instruction to complete execution. The timing diagram in Figure 6-5 shows the case when the peripheral interrupt event occurs in the instruction cycle prior to execution of the two-cycle instruction.

Figure 6-5 shows the timing when a peripheral interrupt is coincident with the first cycle of a two-cycle instruction. In this case, the interrupt process completes as for a one-cycle instruction (see Section 6.3.1 “Interrupt Latency for One-Cycle Instructions”).
6.3.3 Returning from Interrupt

The “Return from Interrupt” instruction, **RETFIE**, exits an interrupt or trap routine. During the first cycle of a **RETFIE** instruction, the upper bits of the PC and the SRL register are popped from the stack. The lower 16 bits of the stacked PC value are popped from the stack during the second cycle. The third instruction cycle is used to fetch the instruction addressed by the updated program counter. This cycle executes as a **NOP**.

Figure 6-6: Return from Interrupt Timing

![Return from Interrupt Timing Diagram](image)

6.3.4 Special Conditions for Interrupt Latency

The dsPIC30F allows the current instruction to complete when a peripheral interrupt source becomes pending. The interrupt latency is the same for both one and two-cycle instructions. However, there are certain conditions that can increase interrupt latency by one cycle, depending on when the interrupt occurs. The user should avoid these conditions if a fixed latency is critical to the application. These conditions are as follows:

- A **MOV.D** instruction is executed that uses PSV to access a value in program memory space.
- An instruction stall cycle is appended to any two-cycle instruction.
- An instruction stall cycle is appended to any one-cycle instruction that performs a PSV access.
- A bit test and skip instruction (**BTSC**, **BTSS**) uses PSV to access a value in the program memory space.
6.4 Interrupt Control and Status Registers

The following registers are associated with the interrupt controller:

- **INTCON1, INTCON2 Registers**
  Global interrupt control functions are derived from these two registers. INTCON1 contains the Interrupt Nesting Disable (NSTDIS) bit, as well as the control and status flags for the processor trap sources. The INTCON2 register controls the external interrupt request signal behavior and the use of the alternate vector table.

- **IFSx: Interrupt Flag Status Registers**
  All interrupt request flags are maintained in the IFSx registers, where ‘x’ denotes the register number. Each source of interrupt has a Status bit, which is set by the respective peripherals or external signal and is cleared via software.

- **IECx: Interrupt Enable Control Registers**
  All Interrupt Enable Control bits are maintained in the IECx registers, where ‘x’ denotes the register number. These control bits are used to individually enable interrupts from the peripherals or external signals.

- **IPCx: Interrupt Priority Control Registers**
  Each user interrupt source can be assigned to one of eight priority levels. The IPC registers are used to set the interrupt priority level for each source of interrupt.

- **SR: CPU Status Register**
  The SR is not specifically part of the interrupt controller hardware, but it contains the IPL<2:0> Status bits (SR<7:5>) that indicate the current CPU priority level. The user may change the current CPU priority level by writing to the IPL bits.

- **CORCON: Core Control Register**
  The CORCON is not specifically part of the interrupt controller hardware, but it contains the IPL3 Status bit which indicates the current CPU priority level. IPL3 is a Read Only bit so that trap events cannot be masked by the user software.

Each register is described in detail on the following pages.

| Note: | The total number and type of interrupt sources will depend on the device variant. Refer to the specific device data sheet for further details. |

6.4.1 Assignment of Interrupts to Control Registers

The interrupt sources are assigned to the IFSx, IECx and IPCx registers in the same sequence that they are listed in Table 6-2. For example, the INT0 (External Interrupt 0) is shown as having vector number and a natural order priority of ‘0’. Thus, the INT0IF Status bit is found in IFS0<0>. The INT0 interrupt uses bit 0 of the IEC0 register as its Enable bit and the IPC0<2:0> bits assign the interrupt priority level for the INT0 interrupt.
### Register 6-1: SR: Status Register (In CPU)

**Upper Byte:**

<table>
<thead>

</table>

bit 7 bit 0

**Advertisements:**

**Note 1:** The IPL<2:0> bits are concatenated with the IPL<3> bit (CORCON<3>) to form the CPU interrupt priority level. The value in parentheses indicates the IPL if IPL<3> = 1.

**Legend:**

- R = Readable bit
- W = Writable bit
- U = Unimplemented bit, read as ‘0’
- C = Bit can be cleared
- -n = Value at POR
- ‘1’ = Bit is set
- ‘0’ = Bit is cleared
- x = Bit is unknown

**Note 2:**

- The IPL<2:0> status bits are read only when NSTDIS = 1 (INTCON1<15>).

6.5 Interrupt Setup Procedures

6.5.1 Initialization

To configure a source of interrupt, follow the steps given below:

1. Set the NSTDIS Control bit (INTCON1<15>) if nested interrupts are not desired.

2. Select the user-assigned priority level for the interrupt source by writing the control bits in
   the appropriate IPCx Control register. The priority level will depend on the specific
   application and type of interrupt source. If multiple priority levels are not desired, the IPCx
   register control bits for all enabled interrupt sources may be programmed to the same
   non-zero value.

3. Clear the interrupt flag status bit associated with the peripheral in the associated IFSx
   Status register.

4. Enable the interrupt source by setting the interrupt enable control bit associated with the
   source in the appropriate IECx Control register.

**Note:** At a device Reset, the IPC registers are initialized, such that all user interrupt
sources are assigned to priority level 4.

6.5.2 Interrupt Service Routine

The method that is used to declare an ISR and initialize the IVT with the correct vector address
will depend on the programming language (i.e., C or assembler) and the language development
tool suite that is used to develop the application. In general, the user must clear the interrupt flag
in the appropriate IFSx register for the source of interrupt that the ISR handles. Otherwise, the
ISR will be re-entered immediately after exiting the routine. If the ISR is coded in assembly
language, it must be terminated using a RETFIE instruction to unstack the saved PC value, SRL
value and old CPU priority level.

6.5.3 Trap Service Routine

A Trap Service Routine (TSR) is coded like an ISR, except that the appropriate trap status flag
in the INTCON1 register must be cleared to avoid re-entry into the TSR.

6.5.4 Interrupt Disable

All user interrupts can be disabled using the following procedure:

1. Push the current SR value onto the software stack using the PUSH instruction.

2. Force the CPU to priority level 7 by inclusive ORing the value 0xE0 with SRL.

To enable user interrupts, the POP instruction may be used to restore the previous SR value.

Note that only user interrupts with a priority level of 7 or less can be disabled. Trap sources
(level 8-level 15) cannot be disabled.

The DISI instruction provides a convenient way to disable interrupts of priority levels 1-6, for a
fixed period of time. Level 7 interrupt sources are not disabled by the DISI instruction.

**Note:** All interrupt sources and their associated control bits may not be available on a particular device. Refer to the device data sheet for details.
6.7 Design Tips

**Question 1:** What happens when two sources of interrupt become pending at the same time and have the same user-assigned priority level?

**Answer:** The interrupt source with the highest natural order priority will take precedence. The natural order priority is determined by the Interrupt Vector Table (IVT) address for that source. Interrupt sources with a smaller IVT address have a higher natural order priority.

**Question 2:** Can the DISI instruction be used to disable all sources of interrupt and traps?

**Answer:** The DISI instruction does not disable traps or priority level 7 interrupt sources. However, the DISI instruction can be used as a convenient way to disable all interrupt sources if no priority level 7 interrupt sources are enabled in the user’s application.
6.8 Related Application Notes

This section lists application notes that are related to this section of the manual. These application notes may not be written specifically for the dsPIC30F Product Family, but the concepts are pertinent and could be used with modification and possible limitations. The current application notes related to the Interrupts module are:

<table>
<thead>
<tr>
<th>Title</th>
<th>Application Note #</th>
</tr>
</thead>
<tbody>
<tr>
<td>No related application notes at this time.</td>
<td></td>
</tr>
</tbody>
</table>

**Note:** Please visit the Microchip web site (www.microchip.com) for additional Application Notes and code examples for the dsPIC30F Family of devices.
Revision History

Revision A
This is the initial released revision of this document.

Revision B
This revision incorporates additional technical content for the dsPIC30F Interrupts module.

Revision C
This revision incorporates all known errata at the time of this document update.

Revision D
This revision includes minor changes to the document text and the addition of a note in 6.1.5 “Interrupt Priority”.
