Introduction

Audio system applications can pose typical producer-consumer problems associated with a real-time system. The timing constraints include latency, sampling rate, sampling period and real-time response. To implement a solution to the audio time challenges, an application typically uses the Ping-Pong data buffer method. The Ping-Pong method uses two buffers: one buffer reads data from the source and another buffer is submitting the data to the destination. When the submission to the destination is complete, the roles of the two buffers are switched. The Ping-Pong is accomplished by modifying the index (pointers) to the buffers.

The following figure represents a typical USB Audio headphone application implementation where the PC (acting as a USB host) streams audio data to the Cortex™-M7 microcontroller (MCU) based audio subsystem. The application updates Buffer1 with streamed in audio data from the USB. The XDMAC sets up the transfer of audio data to the CODEC (through the SSC) by configuring the address of Buffer1 as the source address, and the address of the SSC transmit register (SSC_THR) as the destination address. When the data transmission is completed, the XDMAC switches the source address to Buffer2 (which would be updated by the latest streamed in audio data). When the Buffer2 data transmission is completed, the XDMAC switches the source address to Buffer1, which can be updated by the latest streamed audio data. This process of the XDMAC switching the source address from Buffer1 to Buffer2 continues as the data is streamed in and updated in the buffers while transmitting the data from the buffers to the CODEC to realize the audio playback at the headphone.

1. **Concept**

The XDMAC peripheral provides support to implement the Ping-Pong buffering method through a multiple block data transfer feature. In multiple block data transfer, each block of data can be transferred with different configuration parameters such as, data source, destination address, data size, and trigger source. The XDMAC supports multiple block data transfer through the linked list. An implementation that uses a linked list feature requires the creation of linked list descriptors.

A linked list descriptor contains register settings to transfer a block of memory. When data is transferred using a linked list, the XDMAC fetches the first descriptor from the linked list, copies the register settings to channel registers, and performs the data transfer according to the configuration settings. When the first block transfer is completed, the XDMAC fetches the second descriptor from the linked list, copies the register settings to channel registers, and performs the data transfer according to the configuration settings. This process continues until the end of the linked list. Linked list descriptors are usually stored in internal data memory.
2. Solution
To implement Ping-Pong based audio data buffer handling in the USB Audio headphone application, build an XDMAC circular linked list consisting of two descriptors with the ‘View 1’ type. The ‘View 1’ type descriptor has four members, as shown in the following table.

Table 2-1. View 1 Type Linked List Descriptor

<table>
<thead>
<tr>
<th>MBR_NDA</th>
<th>Next Descriptor Address</th>
</tr>
</thead>
<tbody>
<tr>
<td>MBR_SA</td>
<td>Source Address</td>
</tr>
<tr>
<td>MBR_DA</td>
<td>Destination Address</td>
</tr>
<tr>
<td>MBR_UBC</td>
<td></td>
</tr>
<tr>
<td>UBLEN</td>
<td>Data length in microblocks</td>
</tr>
<tr>
<td>NDE</td>
<td>Next Descriptor Enable</td>
</tr>
<tr>
<td>NSEN</td>
<td>Next Descriptor Source Update</td>
</tr>
<tr>
<td>NDEN</td>
<td>Next Descriptor Source Update</td>
</tr>
<tr>
<td>NVIEW</td>
<td>Next Descriptor View Type</td>
</tr>
</tbody>
</table>

Note: In this application, although the ‘View 0’ type descriptor is sufficient, the ‘View 1’ type descriptor is chosen to demonstrate the use case where one item of control configuration changes (NSEN enabled) from one block to other while another item remains the same (NDEN disabled).

The following figure is a representation of the application buffers used in the Ping-Pong implementation

Figure 2-1. Ping-Pong Audio Data Buffers

Note: The application buffers Buffer1 and Buffer2 are shared between the XDMAC and the USB.
1. Typically, the application maintains the exclusive access to these buffers through a global flag, such as PPFlag, shown in Figure 1.
2. If XDMAC is transmitting Buffer1, it is the responsibility of the application to ensure that the Buffer2 is updated with data from USB before the completion of Buffer1.

The following figure shows the XDMAC circular linked list with two descriptors to implement the Ping-Pong buffering.
1. The next descriptor fields (NDA, NDE, NSEN, NDEN and NVIEW) control the transfer behavior of the next descriptor, not the current descriptor.
   - *Descriptor1* controls the transfer behavior when the first descriptor is completed and the transfer of the second descriptor is to start
   - *Descriptor2* controls the transfer behavior when the second descriptor is completed and the transfer of the first descriptor is to start

2. The NSEN field in both of the linked list descriptors above is set as ‘1’ to enable updates of the channel-specific source address register (XDMAC_CSAx) with the value in the MBR_SA field. This is because at the end of a block transfer, the XDMAC_CSAx would have an invalid address for the next transaction. MBR_SA contains the address of the buffer, which would be the next buffer made ready for transfer.
   - After the end of transmission of *Descriptor1*, XDMAC_CSAx is updated to contain the address of *Buffer2* (pong) from *Buffer1* (ping).
   - After the end of transmission of *Descriptor2*, XDMAC_CSAx is updated to contain the address of *Buffer1* (ping) from *Buffer2* (pong).
3. The NDEN field in both the linked list descriptors above is set as '0' to disable updates of the channel-specific destination address register (XDMAC_CDAx) with the value in the MBR_DA field. This is because at the end of a block transfer, the XDMAC_CDAx would still have a valid address for the next transaction.
   - After the end of transmission of Descriptor1, XDMAC_CDAx contains the address of SSC transmit holding register (SSC THR) and subsequently is not updated.
   - After the end of transmission of Descriptor2, XDMAC_CDAx contains the address of SSC transmit holding register (SSC THR) and subsequently is not updated.

4. To start the data transfer, enable the implemented linked list by directly writing to the channel specific next descriptor control (XDMAC_CNDCx) and address (XDMAC_CNDAx) registers with the values of the first descriptor (NDA, NDE, NSEN, NDEN and NVIEW).

The following figure shows example code to create the circular linked list.
Figure 2-3. Create Circular Linked List

```c
typedef struct {
    /* Next Descriptor Address number. */
    uint32_t mbr_nda;
    /* Microblock Control Member. */
    uint32_t mbr_ubic;
    /* Source Address Member. */
    uint32_t mbr_sa;
    /* Destination Address Member. */
    uint32_t mbr_da;
} lld_view1;

/** Bits per slot */
#define BITS_BY SLOT (16)
/** Total number of buffers */
#define TOTAL_BUFFERS 2
/** Length of a buffer */
#define MAX_DMA_SIZE 240
/** XDMAC Descriptor */
static lld_view1 linklist_write[TOTAL_BUFFERS];
/** Audio Buffer */
static uint16_t Buffer[TOTAL_BUFFERS][MAX_DMA_SIZE*(BITS_BY SLOT / 8)];

for(i = 0; i < TOTAL_BUFFERS; i++)
{
    linklist_write[i].mbr_ubic = XDMAC_UBC_NVIEW_NDVL
        | XDMAC_UBC_NDE_FETCH_EN
        | XDMAC_UBC_NSEN_UPDATED
        | XDMAC_UBC_NDEN_UNCHANGED
        | XDMAC_CUBC_ublen(MAX_DMA_SIZE);
    linklist_write[i].mbr_sa = (uint32_t)&Buffer[i];
    linklist_write[i].mbr_da = (uint32_t)(SSC->SSC_THR);
    if ( i == (TOTAL_BUFFERS - 1 ) )
    {
        linklist_write[i].mbr_nda = (uint32_t)&linklist_write[0];
    }
    else
    {
        linklist_write[i].mbr_nda = (uint32_t)&linklist_write[i+1];
    }
}
```

After initializing the linked list as previously described, and once the corresponding XDMAC channel is enabled, the XDMAC places the contents of Buffer1 onto the SSC transmit register (SSC_THR) according to the configuration parameters. When the Buffer1 transmission is completed, the XDMAC switches to Descriptor2 in the linked list. The source address of the audio data in Descriptor2 points to Buffer2. Once transmission completes, as with earlier descriptor, the XDMAC moves back to the Descriptor1 in the list. The XDMAC switches between the two descriptors (implicitly between the two Ping-Pong audio buffers Buffer1 and Buffer2) while transmitting the audio data through the SSC to the CODEC.

The Microchip Web Site

Microchip provides online support via our web site at http://www.microchip.com/. This web site is used as a means to make files and information easily available to customers. Accessible by using your favorite Internet browser, the web site contains the following information:

- **Product Support** – Data sheets and errata, application notes and sample programs, design resources, user’s guides and hardware support documents, latest software releases and archived software
- **General Technical Support** – Frequently Asked Questions (FAQ), technical support requests, online discussion groups, Microchip consultant program member listing
- **Business of Microchip** – Product selector and ordering guides, latest Microchip press releases, listing of seminars and events, listings of Microchip sales offices, distributors and factory representatives

Customer Change Notification Service

Microchip’s customer notification service helps keep customers current on Microchip products. Subscribers will receive e-mail notification whenever there are changes, updates, revisions or errata related to a specified product family or development tool of interest.

Customer Support

Users of Microchip products can receive assistance through several channels:

- Distributor or Representative
- Local Sales Office
- Field Application Engineer (FAE)
- Technical Support

Customers should contact their distributor, representative or Field Application Engineer (FAE) for support. Local sales offices are also available to help customers. A listing of sales offices and locations is included in the back of this document.

Technical support is available through the web site at: http://www.microchip.com/support

Microchip Devices Code Protection Feature

Note the following details of the code protection feature on Microchip devices:

- Microchip products meet the specification contained in their particular Microchip Data Sheet.
- Microchip believes that its family of products is one of the most secure families of its kind on the market today, when used in the intended manner and under normal conditions.
- There are dishonest and possibly illegal methods used to breach the code protection feature. All of these methods, to our knowledge, require using the Microchip products in a manner outside the operating specifications contained in Microchip’s Data Sheets. Most likely, the person doing so is engaged in theft of intellectual property.
- Microchip is willing to work with the customer who is concerned about the integrity of their code.
• Neither Microchip nor any other semiconductor manufacturer can guarantee the security of their code. Code protection does not mean that we are guaranteeing the product as “unbreakable.”

Code protection is constantly evolving. We at Microchip are committed to continuously improving the code protection features of our products. Attempts to break Microchip’s code protection feature may be a violation of the Digital Millennium Copyright Act. If such acts allow unauthorized access to your software or other copyrighted work, you may have a right to sue for relief under that Act.
