Features

- One of a family of devices with user memory of 1 kilobit to 64 kilobits
- Contactless 13.56MHz RF communications interface
  - ISO/IEC 14443-2:2001 Type B Compliant
  - ISO/IEC 14443-3:2001 Type B Compliant Anticollision Protocol
  - Command set optimized for multi-card RF communications
  - Tolerant of Type A Signaling for multi-protocol applications
- Integrated 82pF tuning capacitor
- User EEPROM memory
  - 8 kilobits configured as eight 128-byte (1-Kbit) user zones
  - Byte, page, and partial page write modes
  - Self-timed write cycle
- 256-byte (2-Kbit) configuration zone
  - User-programmable Application Family Identifier (AFI)
  - User-defined Anticollision Polling Response
  - User-defined keys and passwords
- High-security features
  - 64-bit Mutual Authentication Protocol (under license of ELVA)
  - Encrypted checksum
  - Stream encryption
  - Four key sets for authentication and encryption
  - Eight sets of two 24-bit passwords
  - Password and authentication attempts counters
  - Selectable access rights by zone
  - Anti-tearing function
  - Tamper sensors
- High reliability
  - Endurance: 100,000 write cycles
  - Data retention: 10 years
  - Operating temperature: −25°C to +85°C
1. **Description**

The Atmel® CryptoRF® family integrates a 13.56MHz RF interface into an Atmel CryptoMemory®, resulting in a contactless smart card with advanced security and cryptographic features. This device is optimized as a contactless secure memory, for RF smart cards, and secure data storage, without the requirement of an internal microprocessor.

For communications, the RF interface utilizes the ISO/IEC 14443-2 and -3 Type B bit timing and signal modulation schemes, and the ISO/IEC 14443-3 Slot-MARKER Anticollision Protocol. Data is exchanged half duplex at a 106-Kbit per second rate, with a 2-byte CRC_B providing error detection capability. The maximum communication range between the reader antenna and contactless card is approximately 10cm when used with an RFID reader that transmits the maximum ISO/IEC 14443-2 RF power level. The RF interface powers the other circuits; no battery is required. Full compliance with the ISO/IEC 14443-2 and -3 standards results in anticollision interoperability with the AT88RF020 2-Kbit RFID EEPROM product and provides both a proven RF communication interface and a robust anticollision protocol.

The Atmel AT88SC0808CRF contains eight kilobits of user memory and two kilobits of configuration memory. The two kilobits of configuration memory contain:

- Eight sets of Read/Write passwords
- Four Crypto key sets
- Security access registers for each user zone
- Password/Key registers for each zone

The CryptoRF command set is optimized for a multi-card RF communications environment. A programmable AFI register allows this IC to be used in numerous applications in the same geographic area with seamless discrimination of cards assigned to a particular application during the anticollision process.

2. **Block Diagram**
3. **Communications**

All personalization and communication with this device is performed through the RF interface. The IC includes an integrated tuning capacitor, enabling it to operate with only the addition of a single external coil antenna.

The RF communications interface is fully compliant with the electrical signaling and RF power specifications in ISO/IEC 14443-2:2001 for Type B only. Anticollision operation and frame formatting are compliant with ISO/IEC 14443-3:2001 for Type B only.

ISO/IEC 14443 nomenclature is used in this specification where applicable. The following abbreviations are utilized throughout this document. Additional terms are defined in the section in which they are used.

3.1 **Anticollision Protocol**

When the PICC enters the 13.56MHz RF field of the host reader (PCD), it performs a Power-On Reset (POR) function and waits silently for a valid Type B Polling command. The CryptoRF PICC processes the anti-tearing registers as part of the POR process.

The PCD initiates the anticollision process by issuing an REQB or WUPB command. The WUPB command activates any card (PICC) in the field with a matching AFI code. The REQB command performs the same function but does not affect a PICC in the Halt state. The CryptoRF command set is available only after the anticollision process has been completed.

3.2 **CRC Error Detection**

A 2-byte CRC_B is required in each frame transmitted by the PICC or PCD to permit transmission error detection. The CRC_B is calculated on all of the command and data bytes in the frame. The SOF, EOF, start bits, stop bits, and EGT are not included in the CRC_B calculation. The 2-byte CRC_B follows the data bytes in the frame.

3.3 **Type A Tolerance**

The RF Interface is designed for use in multi-protocol applications. It will not latch or lock up if exposed to Type A signals and will not respond to them. The PICC may reset in the presence of Type A field modulation but is not damaged by exposure to Type A signals.
4. **User Memory**

The EEPROM user memory is divided into eight user zones as shown in Table 4-1. Multiple zones allow for different types of data or files to be stored in different zones. Access to the user zones is allowed only after security requirements have been met. These security requirements are defined by the user in the configuration memory during personalization of the device. The EEPROM memory page length is 16 bytes.

5. **Configuration Memory**

The configuration memory consists of 2048 bits of EEPROM memory used for storing system data, passwords, keys, codes, and security-level definitions for each user zone. Access rights to the configuration zone are defined in the control logic and may not be altered by the user. These access rights include the ability to program certain portions of the configuration memory and then lock the data written through use of the security fuses.

5.1 **Security Fuses**

There are three fuses on the device that must be blown during the device personalization process. Each fuse locks certain portions of the configuration memory as OTP memory. Fuses are designated for the module manufacturer, card manufacturer, and card issuer and must be blown in sequence.
6. **Communication Security**

Communication between the PICC and reader operates in three basic modes:

- **Standard Communication Security Mode** — The default mode for the device after power-up and anticollision.
- **Authentication Communication Security Mode** — Activated by a successful authentication sequence.
- **Encryption Communication Security Mode** — Activated by a successful encryption activation sequence, following a successful authentication.

### 6.2 Memory Access

Depending on the device configuration, the host will carry out the authentication protocol and/or present different passwords for each operation: Read or Write. To insure security between the different user zones (multi-application card), each zone can use a different set of passwords. A specific attempts counter for each password and for the authentication provides protection against systematic attacks.
7. Security Operations

7.1 Anti-tearing

In the event of a power loss during a write cycle, the integrity of the device’s stored data may be recovered. This function is optional — The host may choose to activate the anti-tearing function depending on application requirements.

- When anti-tearing is active, Write commands take longer to execute since more write cycles are required to complete them.
- Data writes are limited to 8-byte pages when anti-tearing is active.

Data is written first to a buffer zone in EEPROM instead of to the intended destination address, but with the same access conditions. The data is then written to the required location. If this second write cycle is interrupted due to a power loss, the device will automatically recover the data from the buffer zone at the next power-up.

7.2 Password Verification

Passwords may be used to protect user zone Read and/or Write access. When a password is presented using the Check Password command, it is memorized and active until power is removed unless a new password is presented or a valid DESELECT or IDLE command is received. Only one password is active at a time, but Write passwords also give Read access.

7.3 Authentication Protocol

The access to a user zone may be protected by an authentication protocol in addition to password dependent rights. Passwords are encrypted in authentication mode.

The authentication success is memorized and active as long as the chip is powered, unless a new authentication is initialized or a valid DESELECT or IDLE command is received. If the new authentication request is not validated, the card loses its previous authentication and it must be presented again. Only the last request is memorized.

7.4 Encryption

The data exchanged between the card and the reader during Read, Write, and Check Password commands may be encrypted to ensure data confidentiality.

The issuer may choose to protect the access to a user zone with an encryption key by settings made in the configuration memory. In that case, activation of the encryption mode is required in order to read/write data in the zone.

The encryption activation success is memorized and active as long as the chip is powered, unless a new initialization is initiated or a valid DESELECT or IDLE command is received. If the new encryption activation request is not validated, the card will no longer encrypt data during Read operations nor will it decrypt data received during Write or Check Password operations.

7.5 Checksum

The PICC implements a data validity check function in the form of a checksum. The checksum may function in standard or cryptographic mode. In the standard mode, the checksum is optional and may be used for transmission error detection. The cryptographic mode is more powerful since it provides data origin authentication capability in the form of a Message Authentication Code (MAC). To write data to the device, the host is required to compute a valid MAC and provide it to the device. If after an in going command the device computes a MAC different from the, MAC transmitted by the host, not only is the command abandoned but the cryptographic mode is also reset. A new authentication is required to reactivate the cryptographic mode.
7.6 Initial Device Programming
CryptoRF is delivered with all security features disabled. To program the polling response or enable the security features of CryptoRF, the device must be personalized by programming several registers. This is accomplished by programming the configuration memory using simple Write and Read commands.

7.7 Transport Password
To gain access to the configuration memory, a transport password known as the secure code must be presented using the Check Password command. The secure code for AT88SC0808CRF is $40 7F AB.

8. Tuning Capacitance
The capacitance between the coil pins AC1 and AC2 is 82pF nominal and may vary ±10% over temperature and process variation.
