Highlights

• One port with 10/100/1000 Ethernet MAC and SGMII interface
• One port with 10/100/1000 Ethernet MAC and configurable RGMII/MII/RMII interface
• IEEE 802.1x access control support
• Five ports with integrated 10/100/1000BASE-T PHY transceivers
• Non-blocking wire-speed Ethernet switching fabric
• Full-featured forwarding and filtering control, including Access Control List (ACL) filtering
• Full VLAN and QoS support
• EtherGreen™ power management features, including low power standby
• Flexible management interface options: SPI, I²C, MIIM, and in-band management via any port
• Commercial/Industrial temperature range support
• 128-pin TQFP-EP (14 x 14mm) RoHS compliant pkg

Target Applications

• Stand-alone 10/100/1000Mbps Ethernet switches
• VoIP infrastructure switches
• Broadband gateways/firewalls
• Wi-Fi access points
• Integrated DSL/cable modems
• Security/surveillance systems
• Industrial control/automation switches
• Networked measurement and control systems

Features

• Switch Management Capabilities
  - 10/100/1000Mbps Ethernet switch basic functions: frame buffer management, address look-up table, queue management, MIB counters
  - Non-blocking store-and-forward switch fabric assures fast packet delivery by utilizing 4096 entry forwarding table with 256kByte frame buffer
  - Jumbo packet support up to 9000 bytes
  - Port mirroring/monitoring/sniffing: ingress and/or egress traffic to any port
  - MIB counters for fully-compliant statistics gathering 34 counters per port
  - Tail tagging mode (one byte added before FCS) support at host port to inform the processor which ingress port receives the packet and its priority
  - Loopback modes for remote failure diagnostics
  - Rapid spanning tree protocol (RSTP) support for topology management and ring/linear recovery
  - Multiple spanning tree protocol (MSTP) support
• One External MAC Port with SGMII
• One External MAC Port with RGMII/MII/RMII
  - RGMII v2.0, RMII v1.2 with 50MHz reference clock input/output option, MII in PHY/MAC mode
• Five Integrated PHY Ports
  - 1000BASE-T/100BASE-TX/10BASE-Tx IEEE 802.3
  - Fast Link-up option significantly reduces link-up time
  - Auto-negotiation and Auto-MDI/MDI-X support
  - On-chip termination resistors and internal biasing for differential pairs to reduce power
  - LinkMD® cable diagnostic capabilities for determining cable opens, shorts, and length
• Advanced Switch Capabilities
  - IEEE 802.1Q VLAN support for 128 active VLAN groups and the full range of 4096 VLAN IDs
  - IEEE 802.1p/Q tag insertion/removal on per port basis
  - VLAN ID on per port or VLAN basis
  - IEEE 802.3x full-duplex flow control and half-duplex back pressure collision control
  - IEEE 802.1X access control (Port-based and MAC address based)
  - IGMP v1/v2/v3 snooping for multicast packet filtering
  - IPv6 multicast listener discovery (MLD) snooping
  - IPv4/IPv6 QoS support, QoS/CoS packet prioritization
  - 802.1p QoS packet classification with 4 priority queues
  - Programmable rate limiting at ingress/egress ports
  - Broadcast storm protection
  - Four priority queues with dynamic packet mapping for IEEE 802.1p, IPv4 DIFFSERV, IPv6 Traffic Class
  - MAC filtering function to filter or forward unknown unicast, multicast and VLAN packets
  - Self-address filtering for implementing ring topologies

• Comprehensive Configuration Registers Access
  - High-speed 4-wire SPI (up to 50MHz), I²C interfaces provide access to all internal registers
  - MII Management (MIIM, MDC/MDIO 2-wire) Interface provides access to all PHY registers
  - In-band management via any of the data ports
  - I/O pin strapping facility to set certain register bits from I/O pins at reset time
  - On-the-fly configurable control registers

• Power Management
  - Energy detect power-down mode on cable disconnect
  - Dynamic clock tree control
  - Unused ports can be individually powered down
  - Full-chip software power-down
  - Wake-on-LAN (WoL) standby power mode with PME interrupt output for system wake upon triggered events
TO OUR VALUED CUSTOMERS

It is our intention to provide our valued customers with the best documentation possible to ensure successful use of your Microchip products. To this end, we will continue to improve our publications to better suit your needs. Our publications will be refined and enhanced as new volumes and updates are introduced.

If you have any questions or comments regarding this publication, please contact the Marketing Communications Department via E-mail at docerrors@microchip.com. We welcome your feedback.

Most Current Documentation
To obtain the most up-to-date version of this documentation, please register at our Worldwide Web site at:

http://www.microchip.com

You can determine the version of a data sheet by examining its literature number found on the bottom outside corner of any page. The last character of the literature number is the version number, (e.g., DS30000000A is version A of document DS30000000).

Errata
An errata sheet, describing minor operational differences from the data sheet and recommended workarounds, may exist for current devices. As device/documentation issues become known to us, we will publish an errata sheet. The errata will specify the revision of silicon and revision of document to which it applies.

To determine if an errata sheet exists for a particular device, please check with one of the following:
- Microchip's Worldwide Web site; http://www.microchip.com
- Your local Microchip sales office (see last page)

When contacting a sales office, please specify which device, revision of silicon and data sheet (include -literature number) you are using.

Customer Notification System
Register on our web site at www.microchip.com to receive the most current information on all of our products.

1.0 PREFACE

1.1 Glossary of Terms

<table>
<thead>
<tr>
<th>Term</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>10BASE-Te</td>
<td>10 Mbps Ethernet, 2.5V signaling, IEEE 802.3 compliant</td>
</tr>
<tr>
<td>100BASE-TX</td>
<td>100 Mbps Fast Ethernet, IEEE 802.3u compliant</td>
</tr>
<tr>
<td>1000BASE-T</td>
<td>1000 Mbps Gigabit Ethernet, IEEE 802.3ab compliant</td>
</tr>
<tr>
<td>ADC</td>
<td>Analog-to-Digital Converter</td>
</tr>
<tr>
<td>AN</td>
<td>Auto-Negotiation</td>
</tr>
<tr>
<td>BLW</td>
<td>Baseline Wander</td>
</tr>
<tr>
<td>BPDU</td>
<td>Bridge Protocol Data Unit. Messages which carry the Spanning Tree Protocol information.</td>
</tr>
<tr>
<td>Byte</td>
<td>8 bits</td>
</tr>
<tr>
<td>CRC</td>
<td>Cyclic Redundancy Check. A common technique for detection data transmission errors. CRC for Ethernet is 32 bits long.</td>
</tr>
<tr>
<td>CSR</td>
<td>Control and Status Registers</td>
</tr>
<tr>
<td>DA</td>
<td>Destination Address</td>
</tr>
<tr>
<td>DWORD</td>
<td>32 bits</td>
</tr>
<tr>
<td>FCS</td>
<td>Frame Check Sequence. The extra checksum characters added to the end of an Ethernet frame, used for error detection and correction.</td>
</tr>
<tr>
<td>FID</td>
<td>Frame or Filter ID. Specifies the frame identifier. Alternately is the filter identifier.</td>
</tr>
<tr>
<td>FIFO</td>
<td>First In First Out buffer</td>
</tr>
<tr>
<td>FSM</td>
<td>Finite State Machine</td>
</tr>
<tr>
<td>GPIO</td>
<td>General Purpose I/O</td>
</tr>
<tr>
<td>Host</td>
<td>External system (includes processor, application software, etc.)</td>
</tr>
<tr>
<td>IPG</td>
<td>Inter-Packet Gap. A time delay between successive data packets mandated by the network standard for protocol reasons.</td>
</tr>
<tr>
<td>Jumbo Packet</td>
<td>A packet larger than the standard Ethernet packet (1518 bytes). Large packet sizes allow for more efficient use of bandwidth, lower overhead, less processing, etc.</td>
</tr>
<tr>
<td>Isb</td>
<td>Least Significant Bit</td>
</tr>
<tr>
<td>LSB</td>
<td>Least Significant Byte</td>
</tr>
<tr>
<td>MAC</td>
<td>Media Access Controller. A functional block responsible for implementing the media access control layer, which is a sublayer of the data link layer.</td>
</tr>
<tr>
<td>MDI</td>
<td>Medium Dependent Interface. An Ethernet port connection that allows network hubs or switches to connect to other hubs or switches without a null-modem, or crossover, cable.</td>
</tr>
<tr>
<td>MDIX</td>
<td>Media Independent Interface with Crossover. An Ethernet port connection that allows networked end stations (i.e., PCs or workstations) to connect to each other using a null-modem, or crossover, cable.</td>
</tr>
<tr>
<td>MIB</td>
<td>Management Information Base. The MIB comprises the management portion of network devices. This can include monitoring traffic levels and faults (statistical), and can also change operating parameters in network nodes (static forwarding addresses).</td>
</tr>
<tr>
<td>MII</td>
<td>Media Independent Interface. The MII accesses PHY registers as defined in the IEEE 802.3 specification.</td>
</tr>
<tr>
<td>MIIM</td>
<td>Media Independent Interface Management</td>
</tr>
<tr>
<td>Term</td>
<td>Description</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
</tr>
<tr>
<td>MLD</td>
<td>Multicast Listening Discovery. This protocol is defined by RFC 3810 and RFC 4604 to establish multicast group membership in IPv6 networks.</td>
</tr>
<tr>
<td>MLT-3</td>
<td>Multi-Level Transmission Encoding (3-Levels). A tri-level encoding method where a change in the logic level represents a code bit “1” and the logic output remaining at the same level represents a code bit “0”.</td>
</tr>
<tr>
<td>msb</td>
<td>Most Significant Bit</td>
</tr>
<tr>
<td>MSB</td>
<td>Most Significant Byte</td>
</tr>
<tr>
<td>NRZ</td>
<td>Non Return to Zero. A type of signal data encoding whereby the signal does not return to a zero state in between bits.</td>
</tr>
<tr>
<td>NRZI</td>
<td>Non Return to Zero Inverted. This encoding method inverts the signal for a “1” and leaves the signal unchanged for a “0”</td>
</tr>
<tr>
<td>N/A</td>
<td>Not Applicable</td>
</tr>
<tr>
<td>NC</td>
<td>No Connect</td>
</tr>
<tr>
<td>OUI</td>
<td>Organizationally Unique Identifier</td>
</tr>
<tr>
<td>PHY</td>
<td>A device or function block which performs the physical layer interface function in a network.</td>
</tr>
<tr>
<td>PLL</td>
<td>Phase Locked Loop. A electronic circuit that controls an oscillator so that it maintains a constant phase angle (i.e., lock) on the frequency of an input, or reference, signal.</td>
</tr>
<tr>
<td>RESERVED</td>
<td>Refers to a reserved bit field or address. Unless otherwise noted, reserved bits must always be zero for write operations. Unless otherwise noted, values are not guaranteed when reading reserved bits. Unless otherwise noted, do not read or write to reserved addresses.</td>
</tr>
<tr>
<td>RTC</td>
<td>Real-Time Clock</td>
</tr>
<tr>
<td>SA</td>
<td>Source Address</td>
</tr>
<tr>
<td>SFD</td>
<td>Start of Frame Delimiter. The 8-bit value indicating the end of the preamble of an Ethernet frame.</td>
</tr>
<tr>
<td>SQE</td>
<td>Signal Quality Error (also known as “heartbeat”)</td>
</tr>
<tr>
<td>SSD</td>
<td>Start of Stream Delimiter</td>
</tr>
<tr>
<td>TCP</td>
<td>Transmission Control Protocol</td>
</tr>
<tr>
<td>UDP</td>
<td>User Datagram Protocol - A connectionless protocol run on top of IP networks</td>
</tr>
<tr>
<td>UTP</td>
<td>Unshielded Twisted Pair. Commonly a cable containing 4 twisted pairs of wire.</td>
</tr>
<tr>
<td>UUID</td>
<td>Universally Unique IDentifier</td>
</tr>
<tr>
<td>VLAN</td>
<td>Virtual Local Area Network</td>
</tr>
<tr>
<td>WORD</td>
<td>16 bits</td>
</tr>
</tbody>
</table>
## 1.2 Buffer Types

### TABLE 1-2: BUFFER TYPES

<table>
<thead>
<tr>
<th>Buffer Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>Input</td>
</tr>
<tr>
<td>IPU</td>
<td>Input with internal pull-up (58 kΩ ±30%)</td>
</tr>
<tr>
<td>IPU/O</td>
<td>Input with internal pull-up (58 kΩ ±30%) during power-up/reset; output pin during normal operation</td>
</tr>
<tr>
<td>IPD</td>
<td>Input with internal pull-down (58 kΩ ±30%)</td>
</tr>
<tr>
<td>IPD/O</td>
<td>Input with internal pull-down (58 kΩ ±30%) during power-up/reset; output pin during normal operation</td>
</tr>
<tr>
<td>O8</td>
<td>Output with 8 mA sink and 8 mA source</td>
</tr>
<tr>
<td>O24</td>
<td>Output with 24 mA sink and 24 mA source</td>
</tr>
<tr>
<td>OPU</td>
<td>Output (8mA) with internal pull-up (58 kΩ ±30%)</td>
</tr>
<tr>
<td>OPD</td>
<td>Output (8mA) with internal pull-down (58 kΩ ±30%)</td>
</tr>
<tr>
<td>SGMII-I</td>
<td>SGMII Input</td>
</tr>
<tr>
<td>SGMII-O</td>
<td>SGMII Output</td>
</tr>
<tr>
<td>AIO</td>
<td>Analog bidirectional</td>
</tr>
<tr>
<td>ICLK</td>
<td>Crystal oscillator input pin</td>
</tr>
<tr>
<td>OCLK</td>
<td>Crystal oscillator output pin</td>
</tr>
<tr>
<td>P</td>
<td>Power</td>
</tr>
<tr>
<td>GND</td>
<td>Ground</td>
</tr>
</tbody>
</table>

**Note:** Refer to Section 6.3, "Electrical Characteristics," on page 179 for the electrical characteristics of the various buffers.
1.3 Register Nomenclature

### TABLE 1-3: REGISTER NOMENCLATURE

<table>
<thead>
<tr>
<th>Register Bit Type Notation</th>
<th>Register Bit Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>R</td>
<td><strong>Read:</strong> A register or bit with this attribute can be read.</td>
</tr>
<tr>
<td>W</td>
<td><strong>Write:</strong> A register or bit with this attribute can be written.</td>
</tr>
<tr>
<td>RO</td>
<td><strong>Read only:</strong> Read only. Writes have no effect.</td>
</tr>
<tr>
<td>RC</td>
<td><strong>Read to Clear:</strong> Contents is cleared after the read. Writes have no effect.</td>
</tr>
<tr>
<td>WO</td>
<td><strong>Write only:</strong> If a register or bit is write-only, reads will return unspecified data.</td>
</tr>
<tr>
<td>WC</td>
<td><strong>Write One to Clear:</strong> Writing a one clears the value. Writing a zero has no effect.</td>
</tr>
<tr>
<td>W0C</td>
<td><strong>Write Zero to Clear:</strong> Writing a zero clears the value. Writing a one has no effect.</td>
</tr>
<tr>
<td>LL</td>
<td><strong>Latch Low:</strong> Applies to certain RO status bits. If a status condition causes this bit to go low, it will maintain the low state until read, even if the status condition changes. A read clears the latch, allowing the bit to go high if dictated by the status condition.</td>
</tr>
<tr>
<td>LH</td>
<td><strong>Latch High:</strong> Applies to certain RO status bits. If a status condition causes this bit to go high, it will maintain the high state until read, even if the status condition changes. A read clears the latch, allowing the bit to go low if dictated by the status condition.</td>
</tr>
<tr>
<td>SC</td>
<td><strong>Self-Clearing:</strong> Contents are self-cleared after the being set. Writes of zero have no effect. Contents can be read.</td>
</tr>
<tr>
<td>RESERVED</td>
<td><strong>Reserved Field:</strong> Reserved fields must be written with zeros, unless otherwise indicated, to ensure future compatibility. The value of reserved bits is not guaranteed on a read.</td>
</tr>
</tbody>
</table>

1.4 References

2.0 INTRODUCTION

2.1 General Description

The KSZ9897S is a highly-integrated, IEEE 802.3 compliant networking device that incorporates a layer-2 managed Gigabit Ethernet switch, five 10BASE-T/100BASE-TX/1000BASE-T physical layer transceivers (PHYs) and associated MAC units, and two individually configurable MAC ports (one SGMII interface, one RGMII/MMII/RMII interface) for direct connection to a host processor/controller, another Ethernet switch, or an Ethernet PHY transceiver. The SGMII port has two modes of operation: SerDes mode (which supports 1000BASE-X fiber) and SGMII mode.

The KSZ9897S is built upon industry-leading Ethernet technology, with features designed to offload host processing and streamline the overall design:

- Non-blocking wire-speed Ethernet switch fabric supports 1 Gbps on RGMII
- Full-featured forwarding and filtering control, including port-based Access Control List (ACL) filtering
- Full VLAN and QoS support
- Traffic prioritization with per-port ingress/egress queues and by traffic classification
- Spanning Tree support
- IEEE 802.1x access control support

A host processor can access all KSZ9897S registers for control over all PHY, MAC, and switch functions. Full register access is available via the integrated SPI or I2C interfaces, and by in-band management via any one of the data ports. PHY register access is provided by a MIIM interface. Flexible digital I/O voltage allows the MAC port to interface directly with a 1.8/2.5/3.3V host processor/controller/FPGA.

Additionally, a robust assortment of power-management features including Wake-on-LAN (WoL) for low power standby operation, have been designed to satisfy energy-efficient system requirements.

The KSZ9897S is available in commercial (0°C to +70°C) and industrial (-40°C to +85°C) temperature ranges. An internal block diagram of the KSZ9897S is shown in Figure 2-1.

FIGURE 2-1: INTERNAL BLOCK DIAGRAM
3.0 PIN DESCRIPTIONS AND CONFIGURATION

3.1 Pin Assignments

The device pin diagram for the KSZ9897S can be seen in Figure 3-1. Table 3-1 provides a KSZ9897S pin assignment table. Pin descriptions are provided in Section 3.2, "Pin Descriptions".

FIGURE 3-1: PIN ASSIGNMENTS (TOP VIEW)

Note: When an "_N" is used at the end of the signal name, it indicates that the signal is active low. For example, RESET_N indicates that the reset signal is active low.

The buffer type for each signal is indicated in the “Buffer Type” column of the pin description tables in Section 3.2, "Pin Descriptions". A description of the buffer types is provided in Section 1.2, "Buffer Types".
Note 3-1 This pin provides configuration strap functions during hardware/software resets. Refer to Section 3.2.1, "Configuration Straps" for additional information.
## 3.2 Pin Descriptions

This section details the functions of the various device signals.

3.2.1 CONFIGURATION STRAPS

The KSZ9897S utilizes configuration strap pins to configure the device for different modes. While \texttt{RESET\_N} is low, these pins are hi-Z. Pull-up/down resistors are used to create high or low states on these pins, which are internally sampled at the rising edge of \texttt{RESET\_N}. All of these pins have a weak internal pull-up or pull-down resistor which provides a default level for strapping. To strap an LED pin low, use a 750\,\Omega to 1\,k\,\Omega external pull-down resistor. To strap a non-LED pin high, use an external 1\,k\,\Omega to 10\,k\,\Omega pull-up resistor to \texttt{VDDIO}. Once \texttt{RESET\_N} is high, all of these pins become driven outputs.

Because the internal pull-up/down resistors are not strong, consideration must be given to any other pull-up/down resistors which may reside on the board or inside a device connected to these pins.

When an LED pin is directly driving an LED, the effect of the LED and LED load resistor on the strapping level must be considered. This is the reason for using a small value resistor to pull an LED pin low. This is especially true when an LED is powered from a voltage that is higher than \texttt{VDDIO}.

The configuration strap pins and their associated functions are detailed in Table 3-3.

4.0 FUNCTIONAL DESCRIPTION

This section provides functional descriptions for the following:

- Physical Layer Transceiver (PHY)
- LEDs
- Media Access Controller (MAC)
- Switch
- NAND Tree Support
- Clocking
- Power
- Power Management
- Management Interface
- In-Band Management
- MAC Interface (Ports 6 and 7)

4.1 Physical Layer Transceiver (PHY)

Ports 1 through 5 include completely integrated triple-speed (10BASE-Te, 100BASE-TX, 1000BASE-T) Ethernet physical layer transceivers for transmission and reception of data over standard four-pair unshielded twisted pair (UTP), CAT-5 or better Ethernet cable.

The device reduces board cost and simplifies board layout by using on-chip termination resistors for the four differential pairs, eliminating the need for external termination resistors. The internal chip termination and biasing provides significant power savings when compared with using external biasing and termination resistors.

The device can automatically detect and correct for differential pair misplacements and polarity reversals, and correct for propagation delay differences between the four differential pairs, as specified in the IEEE 802.3 standard for 1000BASE-T operation.

4.1.1 1000BASE-T TRANSCEIVER

The 1000BASE-T transceiver is based on a mixed-signal/digital signal processing (DSP) architecture, which includes the analog front-end, digital channel equalizers, trellis encoders/decoders, echo cancelers, cross-talk cancelers, a precision clock recovery scheme, and power-efficient line drivers.

4.1.1.1 Analog Echo Cancellation Circuit

In 1000BASE-T mode, the analog echo cancellation circuit helps to reduce the near-end echo. This analog hybrid circuit relieves the burden of the ADC and the adaptive equalizer. This circuit is disabled in 10BASE-Te/100BASE-TX mode.

4.1.1.2 Automatic Gain Control (AGC)

In 1000BASE-T mode, the automatic gain control circuit provides initial gain adjustment to boost up the signal level. This pre-conditioning circuit is used to improve the signal-to-noise ratio of the receive signal.

4.1.1.3 Analog-to-Digital Converter (ADC)

In 1000BASE-T mode, the analog-to-digital converter digitizes the incoming signal. ADC performance is essential to the overall performance of the transceiver. This circuit is disabled in 10BASE-Te/100BASE-TX mode.

4.1.1.4 Timing Recovery Circuit

In 1000BASE-T mode, the mixed signal clock recovery circuit, together with the digital phase locked loop (PLL), is used to recover and track the incoming timing information from the received data. The digital PLL has very low long-term jitter to maximize the signal-to-noise ratio of the receive signal.

The 1000BASE-T slave PHY must transmit the exact receive clock frequency recovered from the received data back to the 1000BASE-T master PHY. Otherwise, the master and slave will not be synchronized after long transmission. This also helps to facilitate echo cancellation and NEXT removal.
4.1.1.5 Adaptive Equalizer

In 1000BASE-T mode, the adaptive equalizer provides the following functions:

- Detection for partial response signaling
- Removal of NEXT and ECHO noise
- Channel equalization

Signal quality is degraded by residual echo that is not removed by the analog hybrid because of impedance mismatch. The device uses a digital echo canceler to further reduce echo components on the receive signal.

In 1000BASE-T mode, data transmission and reception occurs simultaneously on all four pairs of wires (four channels). This results in high-frequency cross-talk coming from adjacent wires. The device uses three NEXT cancelers on each receive channel to minimize the cross-talk induced by the other three channels.

In 10BASE-Te/100BASE-TX mode, the adaptive equalizer needs only to remove the inter-symbol interference and recover the channel loss from the incoming data.

4.1.1.6 Trellis Encoder and Decoder

In 1000BASE-T mode, the transmitted 8-bit data is scrambled into 9-bit symbols and further encoded into 4D-PAM5 symbols. On the receiving side, the idle stream is examined first. The scrambler seed, pair skew, pair order and polarity must be resolved through the logic. The incoming 4D-PAM5 data is then converted into 9-bit symbols and de-scrambled into 8-bit data.

4.1.2 100BASE-TX TRANSCEIVER

4.1.2.1 100BASE-TX Transmit

The 100BASE-TX transmit function performs parallel-to-serial conversion, 4B/5B coding, scrambling, NRZ-to-NRZI conversion, and MLT3 encoding and transmission.

The circuitry starts with a parallel-to-serial conversion, which converts the MII data from the MAC into a 125MHz serial bit stream. The data and control stream is then converted into 4B/5B coding, followed by a scrambler. The serialized data is further converted from NRZ-to-NRZI format, and then transmitted in MLT3 current output. An external ISET resistor sets the output current for the 1:1 transformer ratio.

The output signal has a typical rise/fall time of 4ns and complies with the ANSI TP-PMD standard regarding amplitude balance, overshoot, and timing jitter. The wave-shaped 10BASE-Te output driver is also incorporated into the 100BASE-TX driver.

4.1.2.2 100BASE-TX Receive

The 100BASE-TX receiver function performs adaptive equalization, DC restoration, MLT3-to-NRZI conversion, data and clock recovery, NRZI-to-NRZ conversion, de-scrambling, 4B/5B decoding, and serial-to-parallel conversion.

The receiving side starts with the equalization filter to compensate for inter-symbol interference (ISI) over the twisted pair cable. Since the amplitude loss and phase distortion is a function of the cable length, the equalizer has to adjust its characteristics to optimize performance. In this design, the variable equalizer makes an initial estimation based on comparisons of incoming signal strength against some known cable characteristics, and then tunes itself for optimization. This is an ongoing process and self-adjusts against environmental changes such as temperature variations.

Next, the equalized signal goes through a DC restoration and data conversion block. The DC restoration circuit is used to compensate for the effect of baseline wander and to improve the dynamic range. The differential data conversion circuit converts the MLT3 format back to NRZI. The slicing threshold is also adaptive.

The clock recovery circuit extracts the 125MHz clock from the edges of the NRZI signal. This recovered clock is then used to convert the NRZI signal into the NRZ format. This signal is sent through the de-scrambler followed by the 4B/5B decoder. Finally, the NRZ serial data is converted to an MII format and provided as the input data to the MAC.

4.1.2.3 Scrambler/De-Scrambler

The purpose of the scrambler is to spread the power spectrum of the signal to reduce electromagnetic interference (EMI) and baseline wander. The scrambler is used only for 100BASE-TX.

Transmitted data is scrambled through the use of an 11-bit wide linear feedback shift register (LFSR). The scrambler generates a 2047-bit non-repetitive sequence. Then the receiver de-scrambles the incoming data stream using the same sequence as at the transmitter.
4.1.3 10BASE-Te TRANSCEIVER

10BASE-Te is an energy-efficient version of 10BASE-T which is powered from a 2.5V supply. It has a reduced transmit signal amplitude and requires Cat5 cable. It is inter-operable to 100m with 10BASE-T when Cat5 cable is used.

4.1.3.1 10BASE-Te Transmit

The 10BASE-Te driver is incorporated with the 100BASE-TX driver to allow for transmission using the same magnetics. They are internally wave-shaped and pre-emphasized into outputs with typical 1.75V amplitude (compared to the typical transmit amplitude of 2.5V for 10BASE-T). The harmonic contents are at least 27dB below the fundamental frequency when driven by an all-ones Manchester-encoded signal.

4.1.3.2 10BASE-Te Receive

On the receive side, input buffers and level detecting squelch circuits are employed. A differential input receiver circuit and a phase-locked loop (PLL) perform the decoding function.

The Manchester-encoded data stream is separated into clock signal and NRZ data. A squelch circuit rejects signals with levels less than 400mV or with short pulse widths to prevent noise at the RXP1 or RXM1 input from falsely triggering the decoder. When the input exceeds the squelch limit, the PLL locks onto the incoming signal and the device decodes a data frame. The receiver clock is maintained active during idle periods in between data reception.

4.1.4 AUTO MDI/MDI-X

The automatic MDI/MDI-X feature, also known as auto crossover, eliminates the need to determine whether to use a straight cable or a crossover cable between the device and its link partner. The auto-sense function detects the MDI/MDI-X pair mapping from the link partner, and assigns the MDI/MDI-X pair mapping of the device accordingly. Table 4-1 shows the device’s 10/100/1000 Mbps pin configuration assignments for MDI and MDI-X pin mapping.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Auto MDI/MDI-X is enabled by default. It can be disabled through the port control registers. If Auto MDI/MDI-X is disabled, the port control register can also be used to select between MDI and MDI-X settings.

An isolation transformer with symmetrical transmit and receive data paths is recommended to support Auto MDI/MDI-X.

4.1.5 PAIR-SWAP, ALIGNMENT, AND POLARITY CHECK

In 1000BASE-T mode, the device:

- Detects incorrect channel order and automatically restores the pair order for the A and B pairs. This is also done separately for the C and D pairs. Crossing of A or B pairs to C or D pairs is not corrected.
- Supports 50±10ns difference in propagation delay between pairs of channels in accordance with the IEEE 802.3 standard, and automatically corrects the data skew so the corrected four pairs of data symbols are synchronized.

Incorrect pair polarities of the differential signals are automatically corrected for all speeds.

4.1.6 WAVE SHAPING, SLEW-RATE CONTROL, AND PARTIAL RESPONSE

In communication systems, signal transmission encoding methods are used to provide the noise-shaping feature and to minimize distortion and error in the transmission channel.

- For 1000BASE-T, a special partial-response signaling method is used to provide the bandwidth-limiting feature for the transmission path.
- For 100BASE-TX, a simple slew-rate control method is used to minimize EMI.
- For 10BASE-Te, pre-emphasis is used to extend the signal quality through the cable.
4.1.7 AUTO-NEGOTIATION

The device conforms to the auto-negotiation protocol as described by IEEE 802.3. Auto-negotiation allows each port to operate at either 10BASE-Te, 100BASE-TX or 1000BASE-T by allowing link partners to select the best common mode of operation. During auto-negotiation, the link partners advertise capabilities across the link to each other and then compare their own capabilities with those they received from their link partners. The highest speed and duplex setting that is common to the two link partners is selected as the mode of operation.

The following list shows the speed and duplex operation mode from highest to lowest priority.

- Priority 1: 1000BASE-T, full-duplex
- Priority 2: 1000BASE-T, half-duplex
- Priority 3: 100BASE-TX, full-duplex
- Priority 4: 100BASE-TX, half-duplex
- Priority 5: 10BASE-Te, full-duplex
- Priority 6: 10BASE-Te, half-duplex

If the KSZ9897S link partner doesn't support auto-negotiation or is forced to bypass auto-negotiation for 10BASE-Te and 100BASE-TX modes, the KSZ9897S port sets its operating mode by observing the signal at its receiver. This is known as parallel detection, and allows the KSZ9897S to establish a link by listening for a fixed signal protocol in the absence of the auto-negotiation advertisement protocol.

The auto-negotiation link-up process is shown in Figure 4-1.

**FIGURE 4-1: AUTO-NEGOTIATION AND PARALLEL OPERATION**

For 1000BASE-T mode, auto-negotiation is always required to establish a link. During 1000BASE-T auto-negotiation, the master and slave configuration is first resolved between link partners. Then the link is established with the highest common capabilities between link partners.
Auto-negotiation is enabled by default after power-up or hardware reset. Afterwards, auto-negotiation can be enabled or disabled via bit 12 of the PHY Basic Control Register. If auto-negotiation is disabled, the speed is set by bits 6 and 13 of the PHY Basic Control Register, and the duplex is set by bit 8.

If the speed is changed on the fly, the link goes down and either auto-negotiation or parallel detection initiate until a common speed between the KSZ9897S and its link partner is re-established for a link.

If link is already established and there is no change of speed on the fly, the changes (for example, duplex and pause capabilities) will not take effect unless either auto-negotiation is restarted through bit 9 of the PHY Basic Control Register, or a link-down to link-up transition occurs (i.e. disconnecting and reconnecting the cable).

After auto-negotiation is completed, the link status is updated in the PHY Basic Status Register, and the link partner capabilities are updated in the PHY Auto-Negotiation Link Partner Ability Register, PHY Auto-Negotiation Expansion Status Register, and PHY 1000BASE-T Status Register.

4.1.8 FAST LINK-UP

Link up time is normally determined by the time it takes to complete auto-negotiation. Additional time may be added by the auto MDI/MDI-X feature. The total link up time from power-up or cable connect is typically a second or more.

Fast Link-up mode significantly reduces 100BASE-TX link-up time by disabling both auto-negotiation and auto MDI/MDI-X, and fixing the TX and RX channels. This mode is enabled or disabled by the LED2_1 strapping option. It is not set by registers, so fast link-up is available immediately upon power-up. Fast Link-up is available at power-up only for 100BASE-TX link speed, which is selected by strapping the LED4_0 pin high. Fast Link-up is also available for 10BASE-T, but this link speed must first be selected via a register write.

Fast Link-up is intended for specialized applications where both link partners are known in advance. The link must also be known so that the fixed transmit channel of one device connects to the fixed receive channel of the other device, and vice versa. The TX and RX channel assignments are determined by the MDI/MDI-X strapping option on LED2_0.

If a device in Fast Link-up mode is connected to a normal device (auto-negotiate and auto MDI/MDI-X), there will be no problems linking, but the speed advantage of Fast Link-up will not be realized.

For more information on configuration straps, refer to Section 3.2.1, “Configuration Straps,” on page 16.

4.1.9 LinkMD® CABLE DIAGNOSTICS

The LinkMD® function utilizes Time Domain Reflectometry (TDR) to analyze the cabling for common cabling problems, such as open circuits, short circuits and impedance mismatches.

LinkMD® works by sending a pulse of known amplitude and duration down the MDI or MDI-X pair, and then analyzing the shape of the reflected signal to determine the type of fault. The time duration for the reflected signal to return provides the approximate distance to the cabling fault. The LinkMD® function processes this TDR information and presents it as a numerical value that can be translated to a cable distance.

A LinkMD test is initiated individually for each PHY and for a specific PHY differential pair.

4.1.9.1 Usage

To run a LinkMD test on all four pairs of one PHY, follow this flow.

1. Disable auto-negotiation: Write 0 to of register 0xN100-0xN101 bit 12.

2. Configure register 0xN112-0xN113 to enable master-slave manual configuration mode.

3. Start cable diagnostic by writing 1 to register 0xN124-0xN125 bit 15. This enable bit is self-clearing.

4. Wait (poll) for register 0xN124-0xN125 bit 15 to return 0, which indicates that the cable diagnostic test is completed. Alternatively, wait 250ms.

5. Read cable diagnostic test status in register 0xN124-0xN125 bits [9-8]. The results are:
   a) 00 = normal operation
   b) 01 = open condition detected in cable (valid result)

© 2017-2019 Microchip Technology Inc.
c) 10 = short condition detected in cable (valid result)
d) 11 = cable diagnostic test invalid (test failed)

The ‘11’ case occurs when the PHY is unable to shut down the link partner. In this instance, the test is not run because it would be impossible for the PHY to determine if the detected signal is a reflection of the signal generated or a signal from another source.

6. For status 01 or 10, read the Cable Diagnostic Result in register 0xN124-0xN125 bits [7:0]. Get distance to fault by the following formula:

\[
\text{Distance to fault (meters)} = 0.8 \times (\text{Cable Diagnostic Result} - 22).
\]

7. To test another differential pair on this PHY, change the value of register 0xN124-0xN125 bits [13:12] when initiating the test.

8. Return the registers to their original values and restart auto-negotiation.

The following script will test the four pairs of port 1. For other ports, change the register addresses accordingly.

```
“ww” = write word (16-bits) [register] [data]
“rw” = read word (16-bits) [register]
Values are hexadecimal.

ww 1100 0140     # initialization
ww 1112 1000     # initialization
ww 1124 8000     # initiate test for pair A
sleep 250 msec
rw 1124         # read result for pair A

ww 1124 9000     # initiate test for pair B
sleep 250 msec
rw 1124         # read result for pair B

ww 1124 a000     # initiate test for pair C
sleep 250 msec
rw 1124         # read result for pair C

ww 1124 b000     # initiate test for pair D
sleep 250 msec
rw 1124         # read result for pair D

ww 1112 0700     # return register to default setting
ww 0 1340        # return register to default setting (may vary by application)
```
4.1.10 REMOTE PHY LOOPBACK

This loopback mode checks the line (differential pairs, transformer, RJ-45 connector, Ethernet cable) transmit and receive data paths between the KSZ9897S and its Ethernet PHY link partner, and is supported for 10/100/1000 Mbps at full-duplex.

The loopback data path is shown in Figure 4-2 and functions as follows:

- The Ethernet PHY link partner transmits data to the KSZ9897S PHY port.
- Data received at the external pins of the PHY port is looped back without passing through the MAC and internal switch fabric.
- The same KSZ9897S PHY port transmits data back to the Ethernet PHY link partner.

**FIGURE 4-2: REMOTE PHY LOOPBACK**

The following programming steps and register settings are for remote PHY loopback mode for 1000BASE-T Master Mode, 1000BASE-T Slave Mode, 100BASE-TX Mode, and 10BASE-T Mode.

- **1000BASE-T Master Mode**
  - Set Port N (1-5), PHY 1000BASE-T Control Register = 0x1F00
  - Set Port N (1-5), PHY Remote Loopback Register = 0x01F0
  - Set Port N (1-5), PHY Basic Control Register = 0x1340

- **1000BASE-T Slave Mode**
  - Set Port N (1-5), PHY 1000BASE-T Control Register = 0x1300
  - Set Port N (1-5), PHY Remote Loopback Register = 0x01F0
  - Set Port N (1-5), PHY Basic Control Register = 0x1340

- **100BASE-TX Mode**
  - Set Port N (1-5), PHY Auto-Negotiation Advertisement Register = 0x0181
- Set Port N (1-5), PHY 1000BASE-T Control Register = 0x0C00
- Set Port N (1-5), PHY Remote Loopback Register = 0x01F0
- Set Port N (1-5), PHY Basic Control Register = 0x3300

- 10BASE-T Mode
  - Set Port N (1-5), PHY Auto-Negotiation Advertisement Register = 0x0061
  - Set Port N (1-5), PHY 1000BASE-T Control Register = 0x0C00
  - Set Port N (1-5), PHY Remote Loopback Register = 0x01F0
  - Set Port N (1-5), PHY Basic Control Register = 0x3300

### 4.2 LEDs

Each PHY port has two programmable LED output pins, LEDx_0 and LEDx_1, to indicate the PHY link and activity status. Two different LED modes are available. The LED mode can be changed individually for each PHY port by writing to the PHY Mode bit in the PHY indirect register: MMD 2, address 0, bit 4:

- 1 = Single-LED Mode
- 0 = Tri-Color Dual-LED Mode (Default)

Each LED output pin can directly drive an LED with a series resistor (typically 220Ω to 470Ω). LED outputs are active-low.

#### 4.2.1 SINGLE-LED MODE

In single-LED mode, the LEDx_1 pin indicates the link status while the LEDx_0 pin indicates the activity status, as shown in Figure 4-2.

<table>
<thead>
<tr>
<th>LED Pin</th>
<th>Pin State</th>
<th>Pin LED Definition</th>

<td></td>
<td>Activity (RX,TX)</td>
</tr>
</tbody>
</table>

#### 4.2.2 TRI-COLOR DUAL-LED MODE

In tri-color dual-LED mode, the link and activity status are indicated by the LEDx_1 pin for 1000BASE-T; by the LEDx_0 pin for 100BASE-TX; and by both LEDx_1 and LEDx_0 pins, working in conjunction, for 10BASE-T. This behavior is summarized in Figure 4-3.

4.3 Media Access Controller (MAC)

4.3.1 MAC OPERATION
The device strictly abides by IEEE 802.3 standards to maximize compatibility. Additionally, there is an added MAC filtering function to filter unicast packets. The MAC filtering function is useful in applications, such as VoIP, where restricting certain packets reduces congestion and thus improves performance.

The transmit MAC takes data from the egress buffer and creates full Ethernet frames by adding the preamble and the start-of-frame delimiter ahead of the data, and generates the FCS that is appended to the end of the frame. It also sends flow control packets as needed.

The receive MAC accepts data via the integrated PHY or via the SGMII/MII/RMII/RGMII interface. It decodes the data bytes, strips off the preamble and SFD of each frame. The destination and source addresses and VLAN tag are extracted for use in filtering and address/ID lookup, and the MAC also calculates the CRC of the received frame, which is compared to the FCS field. The MAC can discard frames that are the wrong size, that have an FCS error, or when the source MAC address matches the Switch MAC address.

The receive MAC also implements the Wake on LAN (WoL) feature. This system power saving feature is described in detail in the Section 4.8, "Power Management".

MIB statistics are collected in both receive and transmit directions.

4.3.2 INTER-PACKET GAP (IPG)
If a frame is successfully transmitted, then the minimum 96-bit time for IPG is specified as being between two consecutive packets. If the current packet is experiencing collisions, the minimum 96-bit time for IPG is specified as being from carrier sense (CRS) to the next transmit packet.

4.3.3 BACK-OFF ALGORITHM
The device implements the IEEE standard 802.3 binary exponential back-off algorithm in half-duplex mode. After 16 consecutive collisions, the packet is dropped.

4.3.4 LATE COLLISION
If a transmit packet experiences collisions after 512 bit times of the transmission, the packet is dropped.

4.3.5 LEGAL PACKET SIZE
On all ports, the device discards received packets smaller than 64 bytes (excluding VLAN tag, including FCS) or larger than the maximum size. The default maximum size is the IEEE standard of 1518 bytes, but the device can be configured to accept jumbo packets up to 9000 bytes. Jumbo packet traffic on multiple ports can stress switch resources and cause activation of flow control.

4.3.6 FLOW CONTROL
The device supports standard MAC Control PAUSE (802.3x flow control) frames in both the transmit and receive directions for full-duplex connections.

In the receive direction, if a PAUSE control frame is received on any port, the device will not transmit the next normal frame on that port until the timer, specified in the PAUSE control frame, expires. If another PAUSE frame is received before the current timer expires, the timer will then update with the new value in the second PAUSE frame. During this period (while it is flow controlled), only flow control packets from the device are transmitted.

In the transmit direction, the device has intelligent and efficient ways to determine when to invoke flow control and send PAUSE frames. The flow control is based on availability of the system resources, including available buffers and available transmit queues.

The device issues a PAUSE frame containing the maximum pause time defined in IEEE standard 802.3x. Once the resource is freed up, the device sends out another flow control frame with zero pause time to turn off the flow control (turn on transmission to the port). A hysteresis feature is provided to prevent the flow control mechanism from being constantly activated and deactivated.

4.3.7 HALF-DUPLEX BACK PRESSURE
A half-duplex back pressure option (non-IEEE 802.3 standard) is also provided. The activation and deactivation conditions are the same as in full-duplex mode. If back pressure is required, the device sends preambles to defer the other stations' transmission (carrier sense deference).
To avoid jabber and excessive deference (as defined in the 802.3 standard), after a certain time, the device discontinues the carrier sense and then raises it again quickly. This short silent time (no carrier sense) prevents other stations from sending out packets thus keeping other stations in a carrier sense deferred state. If the port has packets to send during a back pressure situation, the carrier sense type back pressure is interrupted and those packets are transmitted instead. If there are no additional packets to send, carrier sense type back pressure is reactivated again until chip resources free up. If a collision occurs, the binary exponential back-off algorithm is skipped and carrier sense is generated immediately, thus reducing the chance of further collision and carrier sense is maintained to prevent packet reception.

To ensure no packet loss in 10BASE-Te or 100BASE-TX half-duplex modes, the user must enable the following:

- No excessive collision drop (Switch MAC Control 1 Register)
- Back pressure (Port MAC Control 1 Register)

### 4.3.8 FLOW CONTROL AND BACK PRESSURE REGISTERS

Table 4-4 provides a list of flow control and back pressure related registers.

<table>

### 4.3.9 BROADCAST STORM PROTECTION

The device has an intelligent option to protect the switch system from receiving too many broadcast packets. As the broadcast packets are forwarded to all ports except the source port, an excessive number of switch resources (bandwidth and available space in transmit queues) may be utilized. The device has the option to include "multicast packets" for storm control. The broadcast storm rate parameters are programmed globally, and can be enabled or disabled on a per port basis. The rate is based on a 5ms interval for 1000BASE-T, a 50ms interval for 100BASE-TX and a 500ms interval for 10BASE-Te. At the beginning of each interval, the counter is cleared to zero and the rate limit mechanism starts to count the number of bytes during the interval. The rate definition is described in control registers. The default setting equates to a rate of 1%.

### 4.3.10 SELF-ADDRESS FILTERING

Received packets can be filtered (dropped) if their source address matches the device's MAC address. This feature is useful for automatically terminating packets once they have traversed a ring network and returned to their source. It can be enabled on a per-port basis via the Switch Lookup Engine Control 1 Register and Port Control 2 Register.

### 4.4 Switch

#### 4.4.1 SWITCHING ENGINE

A high-performance switching engine is used to move data to and from the MAC's packet buffers. It operates in store and forward mode, while an efficient switching mechanism reduces overall latency. The switching engine has a 256KByte internal frame buffer that is shared between all the ports.
For the majority of switch functions, all of the data ports are treated equally. However, a few functions such as IGMP snooping, 802.1X, forwarding invalid VLAN packets, etc., give special recognition to the host port. Any port (but most commonly port 6 or port 7) may be assigned as the host port by enabling tail tagging mode for that port. Only one port may be a host port.

When a switch receives a non-error packet, it checks the packet's destination MAC address. If the address is known, the packet is forwarded to the output port that is associated with the destination MAC address. The following paragraphs describe the key functions of destination address lookup and source address learning. These processes may be combined with VLAN support and other features, which are described in the subsequent sub-sections.

### 4.4.2 ADDRESS LOOKUP

Destination address lookup is performed in three separate internal address tables in the device:

1. **Address Lookup (ALU) Table**: 4K dynamic + static entries
2. **Static Address Table**: 16 static entries
3. **Reserved Multicast Address Table**: 8 pre-configured static entries

#### 4.4.2.1 Address Lookup (ALU) Table

The Address Lookup (ALU) Table stores MAC addresses and their associated information. This table holds both dynamic and static entries. Dynamic entries are created automatically in hardware, as described in Section 4.4.2.4, "Learning". Static entries are created by management software.

This table is a 4-way associative memory, with 1K buckets, for a total of 4K entries. A hash function translates the received packet's MAC address (and optionally the FID) into a 10-bit index for accessing the table. At each bucket are four fully-associative address entries. All four entries are simultaneously compared to the MAC address (plus optional FID) for a possible match.

Three options are available for the hashing function, as described in Table 4-5. If VLAN is enabled (802.1Q VLAN Enable bit in the Switch Lookup Engine Control 0 Register), the VLAN group (FID) is included in the hashing function along with the MAC address. If VLAN is not enabled the hashing function is applied to MAC address and the FID in the default VLAN (VID=1) which is 0.

#### TABLE 4-5: ADDRESS LOOKUP TABLE HASHING OPTIONS

<table>
<thead>
<tr>
<th>HASH OPTION (Switch Lookup Engine Control 0 Register)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>01b (Default)</td>
<td>A hash algorithm based on the CRC of the MAC address plus FID. The hash algorithm uses the CRC-CCITT polynomial. The input to the hash is reduced to a 16-bit CRC hash value. Bits [9:0] of the hash value plus (binary addition) 7-bit FID (zero extended on the left) are used as an index to the table. The CRC-CCITT polynomial is: $X^{16}+X^{12}+X^5+1$.</td>
</tr>
<tr>
<td>10b</td>
<td>An XOR algorithm based on 16 bits of the XOR of the triple-folded MAC address. Bits [9:0] of the XOR value plus 7-bit FID (left-extended) are used to index the table.</td>
</tr>
<tr>
<td>00b or 11b</td>
<td>A direct algorithm. The 10 least significant bits of the MAC address plus 7 bit FID are used to index the table.</td>
</tr>
</tbody>
</table>

#### 4.4.2.2 Static Address Table

The 16-entry Static Address Table is typically used to hold multicast addresses, but is not limited to this. As with static entries in the ALU table, entries in the Static Address Table are created by management software. It serves the same function as static entries that are created in the ALU table, so its use is optional.

#### 4.4.2.3 Reserved Multicast Address Table

The Reserved Multicast Address Table holds 8 pre-configured address entries, as defined in Table 4-6. This table is an optional feature that is disabled at power-on. If desired, the forwarding ports may be modified.
If a match is found in one of the tables, then the destination port is read from that table entry. If a match is found in more than one table, static entries will take priority over dynamic entries.

### 4.4.2.4 Learning

The internal lookup engine updates the ALU table with a new dynamic entry if the following conditions are met:

- The received packet's source address (SA) does not exist in the lookup table.
- The received packet has no errors, and the packet size is of legal length.
- The received packet has a unicast SA.

The lookup engine inserts the qualified SA into the table, along with the port number and age count. If all four table entries are valid, the oldest of the (up to four) dynamic entries may be deleted to make room for the new entry. Static entries are never deleted by the learning process. If all four entries are static entries, the address is not learned but an interrupt is generated and the table index number is made available to the interrupt service routine.

### 4.4.2.5 Migration

The internal lookup engine also monitors whether a station has moved. If a station has moved, it updates the ALU table accordingly. Migration happens when the following conditions are met:

- The received packet's SA is in the table but the associated source port information is different.
- The received packet has no receiving errors, and the packet size is of legal length.

The lookup engine updates the existing record in the table with the new source port information.

### 4.4.2.6 Aging

The lookup engine updates the age count information of a dynamic record in the ALU table whenever the corresponding SA appears. The age count is used in the aging process. If a record is not updated for a period of time, the lookup engine removes the record from the table. The lookup engine constantly performs the aging process and continuously removes aging records. The aging period is about 300 seconds (±75 seconds) and can be configured longer or shorter (1 second to 30 minutes). This feature can be enabled or disabled. Static entries are exempt from the aging process.

</tbody>
</table>
4.4.2.7 Forwarding

The device forwards packets using the algorithm that is depicted in Figure 4-3. Figure 4-3 shows stage one of the forwarding algorithm where the search engine looks up the VLAN ID, static table, and dynamic table for the destination address, and comes up with "port to forward 1" (PTF1). PTF1 is then further modified by spanning tree, IGMP snooping, port mirroring, and port VLAN processes.

The ACL process works in parallel with the flow outlined above. The authentication and ACL processes have the highest priority in the forwarding process, and the ACL result may override the result of the above flow. The output of the ACL process is the final "port-to-forward 2" (PTF2) destination port(s).

The device will not forward the following packets:

- Error packets: These include framing errors, frame check sequence (FCS) errors, alignment errors, and illegal size packet errors.
- MAC Control PAUSE frames: The device intercepts these packets and performs full duplex flow control accordingly.
- "Local" packets: Based on destination address (DA) lookup. If the destination port from the lookup table matches the port from which the packet originated, the packet is defined as "local".
- In-Band Management packets.

4.4.3 IEEE 802.1Q VLAN

Virtual LAN is a means of segregating a physical network into multiple virtual networks whereby traffic may be confined to specific subsets of the greater network. IEEE 802.1Q defines a VLAN protocol using a 4-byte tag that is added to the Ethernet frame header. The device supports port-based and tag-based VLANs, including tagging, un-tagging, forwarding and filtering.

4.4.3.1 Non-Tag Port-Based VLAN

The simplest VLAN method establishes forwarding restrictions on a port-by-port basis without using VLAN tags. There is a register for each ingress port that is used to specify the allowed forwarding ports. An incoming packet is restricted from being forwarded to any egress port that is disallowed for that ingress port. The settings are made in the Port Control 1 Register. This function is always enabled; it is not enabled and disabled by the 802.1Q VLAN Enable bit in the Switch Lookup Engine Control 0 Register. The default setting is to allow all ingress-to-egress port paths.

4.4.3.2 Tag-Based VLAN

When 802.1Q VLAN is enabled, an internal VLAN Table with 4k entries is used to a store port membership list, VLAN group ID (FID) and additional information relating to each VLAN. This table must be set up by an administrator prior to enabling 802.1Q VLAN. Enabling is done by setting the 802.1Q VLAN Enable bit in the Switch Lookup Engine Control 0 Register.

In 802.1Q VLAN mode, the lookup process starts with VLAN Table lookup, using the tag's VID as the address. The first step is to determine whether the VID is valid. If the VID is not valid, the packet is dropped and its address is not learned. Alternatively, unknown VID packets may be forwarded to pre-defined ports or to the host port. If the VID is valid, the FID is retrieved for further lookup. The FID + Destination Address (hashed(DA) + FID) are used to determine the destination port. The FID + Source Address (hashed(SA) + FID) are used for address learning (see Table 4-9 and Table 4-10).
The hashed(DA) + FID are hashed and used for forwarding lookup in the Address Lookup and Static Address Tables. For a successful address table lookup, the FID fields must also match. If the match fails, the packet is broadcast to all the VLAN port members defined in the VLAN Table entry. If there is a match and egress VLAN filtering is enabled, the packet is forwarded to those ports that are in both the address table port forwarding list and the VLAN table port membership list.

A similar address table lookup is performed using the hashed(SA) + FID. If the lookup fails, the FID and SA are learned.

If a non-tagged or null-VID-tagged packet is received, the ingress port default VID (Port Default Tag 0 Register and Port Default Tag 1 Register) is used for lookup.

Table 4-8 details the forwarding and discarding actions that are taken for the various VLAN scenarios. The first entry in the table is explained by the fact that VLAN Table lookup is enabled even when 802.1Q VLAN is not enabled. Notice that in the Port Default Tag 0 Register and Port Default Tag 1 Register, the port default VID is 1 for each port. Correspondingly, the VLAN port membership list in the VLAN Table entry for VID=1 is pre-configured at power-on to all ones. This provides the standard Ethernet switch behavior of broadcasting all packets with unknown destination address. If the VLAN table entry # 1 is changed, or if the port default VID is changed, this may affect the forwarding action for “unknown packets” even when VLAN is not enabled.

It should also be noted that the default values of the Egress VLAN Filtering bits are zero. These bits are zero only for backwards compatibility with previous “KSZ” switches. The resulting switch behavior, in the event of a successful VLAN and ALU lookups, is to forward the packet to the ports in the address table port forwarding list, without regard to the VLAN port membership list. It is suggested that the Egress VLAN Filtering bits be set to one so that the VLAN port membership list from the VLAN Table will be used to qualify the forwarding determined from the address lookup.

**Note:** “(def)” indicates the default power-up value.

**Note 4-1** VLAN Enable is bit 7 in the Switch Lookup Engine Control 0 Register

**Note 4-2** VLAN Match/Valid indicates when the VLAN Table entry is valid

**Note 4-3** Forward Option is a bit in the VLAN Table Entry 0 Register

**Note 4-4** Egress VLAN Filtering are bits 5 and 4 in the Switch Lookup Engine Control 2 Register

**Note 4-5** Unknown VID Forwarding is in the Unknown VLAN ID Control Register

**Note 4-6** Drop Invalid VID is bit 6 in the Switch Lookup Engine Control 0 Register

**Note 4-7** ALU Match/Valid indicates when the Address Lookup is a success

Table 4-9 describes in more detail the address lookup process that follows the VLAN Table lookup. Lookup occurs in both the Address Lookup Table and the Static Address Table simultaneously, and the resulting action depends on the results of the two lookups.

**TABLE 4-9: HASHED(DA) + FID LOOKUP IN VLAN MODE**

A source address (SA) lookup is also performed in the Address Lookup Table. SA lookup also performs SA filtering and MAC priority when the address is hit. **Table 4-10** describes how learning is performed in the Address Lookup Table when a successful VLAN table lookup has been done and the no matching static entry is found in the Address Lookup Table or the Static Address Table.

**TABLE 4-10: HASHED(SA) + FID LOOKUP IN VLAN MODE**

</table>
4.4.3.2.1 Tag Insertion and Removal

Tag insertion is enabled on all ports when the VLAN feature is enabled. At the ingress port, untagged packets are tagged with the ingress port's default tag. The default tag is separately programmable for each port. The switch does not add tags to already tagged packets unless double tagging is enabled.

At the egress port, tagged packets will have their 802.1Q VLAN tags removed if un-tagging is enabled in the VLAN table entry. Untagged packets will not be modified if 802.1Q is enabled.

4.4.3.2.2 Double Tagging

The switch supports double tagging, also known as Q-in-Q or VLAN stacking. This feature can be used for service providers to append a second VLAN tag in addition to a first VLAN tag applied by the customer. VLAN support can be enabled either with or without double tagging. When double tagging is enabled, the outer tag is recognized and is used for VLAN and address lookup instead of the inner tag. The outer tag precedes the inner tag in the frame header: the outer tag is located immediately after the source address, and contains a different Tag Protocol Identifier (TPID) value than the inner tag.

Additional controls are available for full control of the VLAN function. Some of these features can be enabled on a per-port basis, while others are global:

- **Ingress VLAN Filtering**: Discard packet if VID port membership in VLAN table does not include the ingress port.
- **Discard non PVID Packet**: Discard packet if VID does not match the ingress port default VID.
- **Discard un-tagged Packet**: Discard any received packet without a tag.
- **Drop tag**: Drops the packet if it is VLAN tagged.
- **Unknown VID Forward**: Forward to a fixed set of ports if VLAN lookup fails.
- **Drop unknown VID**: Additional options for unknown VID packets: discard or forward to the host port.
- **Null VID Replacement**: Replace a null VID with the ingress port default VID.
- **PVID Replacement**: Replace a non-null VID with the ingress port default VID.
- **Double Tag Mcast Trap**: In double tag mode, trap all reserved multicast packets and forward to the host port.

4.4.3.3 VLAN Registers

Table 4-11 provides a list of VLAN related registers.

4.4.4 QUALITY-OF-SERVICE (QOS) PRIORITY SUPPORT

The device provides quality-of-service (QoS) for applications such as VoIP. There are multiple methods for assigning priority to ingress packets. Depending on the packet prioritization method, the packet priority levels are mapped to the egress queues for each port. Each port can be configured for 1, 2, and 4 egress queues, which are prioritized. The default is 1 queue per port.

When configured for 4 priority queues, Queue 3 is the highest priority queue and Queue 0 is the lowest priority. Likewise, for a 2-queue configuration, Queue 1 is the highest priority queue. If a port is not configured as 2 or 4 queues, then high priority and low priority packets have equal priority in the single transmit queue.

There is an additional option for every port to select either to always deliver packets from the highest priority queue first, or use weighted round robin queuing amongst the multiple queues. This is described later in Section 4.4.13, “Scheduling and Rate Limiting”.

4.4.4.1 Port-Based Priority

With port-based priority, each ingress port is individually classified as a specific priority level. All packets received at the high-priority receiving port are marked as high priority and are sent to the high-priority transmit queue if the corresponding transmit queue is split into 2 or 4 queues.

4.4.4.2 IEEE 802.1p-Based Priority

For IEEE 802.1p-based priority, the device examines the ingress packets to determine whether they are tagged. If tagged, the 3-bit PCP priority field in the VLAN tag is retrieved and used to look up the “priority mapping” value. The “priority mapping” value is programmable.

Figure 4-4 illustrates how the 802.1p priority field is embedded in the 802.1Q VLAN tag.

FIGURE 4-4: 802.1P PRIORITY FIELD FORMAT

4.4.4.3 IEEE 802.1p Priority Field Re-Mapping

This is a QoS feature that allows the device to set the “User Priority Ceiling” at any ingress port. If the ingress packet's priority field has a higher priority value than the default tag's priority field of the ingress port, the packet's priority field is replaced with the default tag's priority field.

4.4.4.4 DiffServ (DSCP) Priority (IP)

DiffServ-based priority from the DSCP field in the IP header can be used to determine packet priority. The 6-bit DSCP value is used as an index to a set of registers which translate the 6-bit DSCP value to a 2-bit value that specifies one of the 4 (or 2) queues. These registers are fully programmable.

4.4.4.5 ACL Priority

The Access Control List (ACL) Filtering feature can also be used to assign priority to received packets. This is discussed in Section 4.4.16, “Access Control List (ACL) Filtering”.

© 2017-2019 Microchip Technology Inc.
4.4.5 TRAFFIC CONDITIONING & POLICING

4.4.5.1 Two Rate Three Color Marker

The Two Rate Three Color Marker meters an IP packet stream and marks its packets green, yellow, or red. A packet is marked red if it exceeds the Peak Information Rate (PIR). Otherwise, it is marked either yellow or green depending on whether it exceeds or doesn't exceed the Committed Information Rate (CIR).

The Meter operates in one of two modes. In the Color-Blind mode, the Meter assumes that the packet stream is uncolored. In the Color-Aware mode, the Meter assumes that some preceding entity has pre-colored the incoming packet stream so that each packet is green, yellow, or red. The Marker (re)colors an IP packet according to the results of the Meter.

4.4.5.2 Weighted Random Early Detection (WRED)

The WRED feature monitors the average queue size of packet memory and ingress queue size of each traffic class, and drops packets based on memory and queue utilization. If the buffers are almost empty, all incoming traffic is accepted. As the buffer utilization increases, the probability for dropping an incoming packet also increases.

WRED is intended to avoid the problem of global synchronization. Global synchronization can occur when a switch becomes congested and begins dropping incoming packets at once. For TCP streams, packet drops invoke the TCP congestion control mechanism, which reduce the transmission rate until there are no more packet drops. If there are many TCP streams and their congestion control mechanisms act in unison, this can cause an undesirable oscillation in traffic rates. By selectively dropping some packets early rather than waiting until the buffer is full, WRED avoids dropping large numbers of packets at once and minimizes the chances of global synchronization.

The packet drop probability is based on the minimum threshold, maximum threshold, and a probability multiplier. When the average queue depth is above the minimum threshold, packets start getting dropped. The rate of packet drop increases linearly as the average queue size increases until the average queue size reaches the maximum threshold. The probability multiplier is the fraction of packets dropped when the average queue depth is at the maximum threshold. When the average queue size is above the maximum threshold, all packets are dropped.

4.4.6 SPANNING TREE SUPPORT

To support spanning tree, one port is the designated port for the host processor, which is defined as the port for which tail tagging is enabled. Each of the other ports can be configured in one of the five spanning tree states via “transmit enable”, “receive enable” and “learning disable” register bits. Table 4-12 shows the setting and software actions taken for each of the five spanning tree states.

<table>
<thead>
<tr>
<th>Disable State</th>
<th>Port Setting</th>
<th>Software Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>The port should not forward or receive any packets. Learning is disabled.</td>
<td>transmit enable = 0 receive enable = 0 learning disable = 1</td>
<td>The processor should not send any packets to the port. The switch may still send specific packets to the processor (packets that match some entries in the &quot;Static MAC Table&quot; with &quot;overriding bit&quot; set) and the processor should discard those packets. Address learning is disabled on the port in this state.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Blocking State</th>
<th>Port Setting</th>
<th>Software Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Only packets to the processor are forwarded. Learning is disabled.</td>
<td>transmit enable = 0 receive enable = 0 learning disable = 1</td>
<td>The processor should not send any packets to the port(s) in this state. The processor should program the &quot;Static MAC Table&quot; with the entries that it needs to receive (for example, BPDU packets). The &quot;overriding&quot; bit should also be set so that the switch will forward those specific packets to the processor. Address learning is disabled on the port in this state.</td>
</tr>
</tbody>
</table>
There are three operational states assigned to each port for the Rapid Spanning Tree Protocol (RSTP):

1. **Discarding State**
   - Discarding ports do not participate in the active topology and do not learn MAC addresses.
   - Port setting: transmit enable = "0", receive enable = "0", learning disable = "1".
   - Software action: The host processor should program the “Static MAC Table” with the entries that it needs to receive (for example, BPDU packets). The “overriding” bit should be set so that the switch will forward those specific packets to the processor. The processor may send packets to the port(s) in this state. Address learning is disabled on the port in this state.

2. **Learning State**
   - Only packets to and from the processor are forwarded. Learning is enabled.
   - Port setting: transmit enable = "0", receive enable = "0", learning disable = "0".
   - Software action: The processor should program the “Static MAC Table” with the entries that it needs to receive (for example, BPDU packets). The “overriding” bit should be set so that the switch will forward those specific packets to the processor. The processor may send packets to the port(s) in this state. Address learning is enabled on the port in this state.

3. **Forwarding State**
   - Packets are forwarded and received normally. Learning is enabled.
   - Port setting: transmit enable = "1", receive enable = "1", learning disable = "0".
   - Software action: The processor programs the “Static MAC Table” with the entries that it needs to receive (for example, BPDU packets). The “overriding” bit is set so that the switch forwards those specific packets to the processor. The processor can send packets to the port(s) in this state. Address learning is enabled on the port in this state.

### TABLE 4-12: SPANNING TREE STATES (CONTINUED)

<table>
<thead>
<tr>

<td>The processor programs the “Static MAC Table” with the entries that it needs to receive (for example, BPDU packets). The “overriding” bit is set so that the switch forwards those specific packets to the processor. The processor can send packets to the port(s) in this state. Address learning is enabled on the port in this state.</td>
</tr>
<tr>
<td></td>
<td>receive enable = 1</td>
<td></td>
</tr>
<tr>
<td></td>
<td>learning disable = 0</td>
<td></td>
</tr>
</tbody>
</table>

### Notes

- Discarding state: the state includes three states of the disable, blocking and listening of STP.
- Software action: The host processor should not send any packets to the port. The switch may still send specific packets to the processor (packets that match some entries in the static table with “overriding bit” set) and the processor should discard those packets. When the port's learning capability (learning disable = "1") is disabled, port related entries in the ALU table and static MAC table can be rapidly flushed.
• Software action: The host processor should program the Static Address Table with the entries that it needs to receive (e.g., BPDU packets). The "overriding" bit should be set so that the switch will forward those specific packets to the processor. The processor may send packets to the port(s) in this state (see Section 4.4.9, "Tail Tagging Mode" for details). Address learning is enabled on the port in this state.

RSTP uses only one type of BPDU called RSTP BPDU. They are similar to STP configuration BPDU with the exception of a type field set to "version 2" for RSTP and "version 0" for STP, and a flag field carrying additional information.

4.4.8 MULTIPLE SPANNING TREE SUPPORT

Multiple Spanning Tree Protocol (MSTP) is an extension of RSTP that allows different VLANs to have different spanning tree configurations. The VLAN Table, Address Lookup Table and Static Address Table all contain a 3-bit field which can be used to specify one of eight spanning trees. Each port contains state registers for specifying unique states for each of the spanning trees.

4.4.9 TAIL TAGGING MODE

Tail tagging is a method to communicate ingress and egress port information between the host processor and the switch. It is useful for spanning tree protocol, IGMP/MLD snooping, and other applications. As shown in Figure 4-5, the tail tag is inserted at the end of the packet, between the payload and the 4-byte CRC / FCS.

![FIGURE 4-5: TAIL TAG FRAME FORMAT](image)

<table>
<thead>
<tr>
<th>Bytes</th>
<th>Description</th>
<th>Bits</th>
</tr>
</thead>
<tbody>
<tr>
<td>6</td>
<td>DEST ADDRESS</td>
<td>7</td>
</tr>
<tr>
<td>6</td>
<td>SOURCE ADDRESS</td>
<td>0 = Is not a PTP message. A 4-byte receive timestamp has not been added. 1 = Is a PTP message. A 4-byte timestamp has been added before the tail tag.</td>
</tr>
<tr>
<td>4</td>
<td>802.1Q TAG</td>
<td>6:3</td>
</tr>
<tr>
<td>2</td>
<td>ETYPETag LENGTH</td>
<td>Reserved</td>
</tr>
<tr>
<td>2</td>
<td>PAYLOAD</td>
<td>2:0</td>
</tr>
<tr>
<td>1</td>
<td>TAIL TAG</td>
<td>Received Port</td>
</tr>
<tr>
<td>4</td>
<td>FCS</td>
<td>000 = Packet received at Port 1 001 = Packet received at Port 2 010 = Packet received at Port 3 011 = Packet received at Port 4 100 = Packet received at Port 5 101 = Packet received at Port 6 110 = Packet received at Port 7</td>
</tr>
</tbody>
</table>

When the switch forwards a received packet to the host port, one tail tagging byte is added to the packet by the switch to indicate to the host processor the port that the packet was received on. The format is shown in Table 4-13.

**TABLE 4-13: RECEIVE TAIL TAG FORMAT (FROM SWITCH TO HOST)**

<table>
<thead>
<tr>
<th>Bits</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>7</td>
<td>PTP Message Indication</td>
</tr>
<tr>
<td>0</td>
<td>Is not a PTP message. A 4-byte receive timestamp has not been added.</td>
</tr>
<tr>
<td>1</td>
<td>Is a PTP message. A 4-byte timestamp has been added before the tail tag.</td>
</tr>
<tr>
<td>6:3</td>
<td>Reserved</td>
</tr>
<tr>
<td>2:0</td>
<td>Received Port</td>
</tr>
<tr>
<td>000</td>
<td>Packet received at Port 1</td>
</tr>
<tr>
<td>001</td>
<td>Packet received at Port 2</td>
</tr>
<tr>
<td>010</td>
<td>Packet received at Port 3</td>
</tr>
<tr>
<td>011</td>
<td>Packet received at Port 4</td>
</tr>
<tr>
<td>100</td>

</tr>
<tr>
<td>101</td>
<td>Packet received at Port 6</td>
</tr>
<tr>
<td>110</td>
<td>Packet received at Port 7</td>
</tr>
</tbody>
</table>

In the opposite direction, the host processor must add two tail tag bytes to each packet that it sends to the switch to indicate the intended egress ports. When multiple priority queues are enabled, the tail tag is also used to indicate the priority queue. The format is shown in Table 4-14. This tail tag is removed by the switch before the packet leaves the switch. If the Lookup bit (bit 10) is set, packet forwarding follows the standard forwarding process, and bits [9:0] are ignored. When the Lookup bit is not set, bits [8:0] determine the forwarding ports and priority queue, while the Override bit (bit 9) determines whether port blocking is overridden.

Tail tagging applies only to the host port, never to any other ports of the switch.
By default, tail tagging is disabled. To enable it, set the Tail Tag Enable bit in one of the Port Operation Control 0 Register at address 0xN020 for port "N". When this bit is set for one port, that port is referred to as the "host" port. Do not set the Tail Tag Enable bit for more than one port.

### TABLE 4-14: TRANSMIT TAIL TAG FORMAT (FROM HOST TO SWITCH)

<table>
<thead>
<tr>
<th>Bits</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>15:11</td>
<td>Reserved</td>
</tr>
</tbody>
</table>
| 10    | Lookup
| 0 = Port forwarding is determined by tail tag bits [9:0] below.
| 1 = Tail tag bits [9:0] are ignored and port forwarding is determined by the standard switch forwarding process (address lookup, VLAN, etc.) |
| 9     | Port Blocking Override
| 0 = Port forwarding is determined by tail tag bits [9:0] below.
| 1 = Tail tag bits [9:0] are ignored and port forwarding is determined by the standard switch forwarding process (address lookup, VLAN, etc.) |
| 8:7   | Egress priority (0 to 3)                                                    |
| 6     | Forward to Port 7                                                           |
| 5     | Forward to Port 6                                                           |
| 4     | Forward to Port 5                                                           |
| 3     | Forward to Port 4                                                           |
| 2     | Forward to Port 3                                                           |
| 1     | Forward to Port 2                                                           |
| 0     | Forward to Port 1                                                           |

By default, tail tagging is disabled. To enable it, set the Tail Tag Enable bit in one of the Port Operation Control 0 Register at address 0xN020 for port "N". When this bit is set for one port, that port is referred to as the "host" port. Do not set the Tail Tag Enable bit for more than one port.

#### 4.4.10 IGMP SUPPORT

For Internet Group Management Protocol (IGMP) support in Layer 2, the device provides two components:

- "IGMP" Snooping
- "Multicast Address Insertion" in the Static MAC Table

#### 4.4.10.1 "IGMP" Snooping

The device traps IGMP packets and forwards them only to the processor (host port). The IGMP packets are identified as IP packets (either Ethernet IP packets, or IEEE 802.3 SNAP IP packets) with IP version = 0x4 and protocol version number = 0x2.

**Note:** The port for which Tail Tagging Mode is enabled is the host port.

#### 4.4.10.2 "Multicast Address Insertion" in the Static MAC Table

Once the multicast address is programmed in the Static Address Table or Address Lookup Table, the multicast session is trimmed to the subscribed ports, instead of broadcasting to all ports.

So that the host processor knows which port the IGMP packet was received on, Tail Tagging Mode must be enabled.

#### 4.4.11 IPV6 MLD SNOOPING

The device traps IPv6 Multicast Listener Discovery (MLD) packets and forwards them only to the processor (host port).

#### 4.4.12 PORT MIRRORING

The device supports "port mirroring" comprehensively as:

- "Receive Only" Mirror-on-a-Port
- "Transmit Only" Mirror-on-a-Port
- "Receive and Transmit" Mirror-on-a-Port
4.4.12.1 “Receive Only” Mirror-on-a-Port
All the packets received on the port are mirrored on the sniffer port. For example, 1 is programmed to be “receive sniff” and the host port is programmed to be the “sniffer”. A packet received on port 1 is destined to port 2 after the internal lookup. The packet is forwarded to both port 2 and the host port. The device can optionally even forward “bad” received packets to the “sniffer port”.

4.4.12.2 “Transmit Only” Mirror-on-a-Port
All the packets transmitted on the port are mirrored on the sniffer port. For example, port 1 is programmed to be “transmit sniff” and the host port is programmed to be the “sniffer port”. A packet received on port 2 is destined to port 1 after the internal lookup. The device forwards the packet to both port 1 and the host port.

4.4.12.3 “Receive and Transmit” Mirror-on-a-Port
All the packets received on port A and transmitted on port B are mirrored on the sniffer port. For example, port 1 is programmed to be “receive sniff”, port 2 is programmed to be “transmit sniff”, and the host port is programmed to be the “sniffer port”. A packet received on port 1 is destined to port 2 after the internal lookup. The device forwards the packet to both port 2 and the host port.

Multiple ports can be selected as “receive sniff” or “transmit sniff”. In addition, any port can be selected as the “sniffer port”.

4.4.13 SCHEDULING AND RATE LIMITING
Each device port has two egress packet scheduling options, which can be applied when the port is configured for two or four queues. Additionally, each port has ingress and egress rate limiter features.

4.4.13.1 Strict Priority Scheduling
When an egress port is configured as two or four queues, and strict priority scheduling is selected, each queue will take absolute priority over all lower priority queues. If a packet is available to transmit from queue 3 (the highest priority queue), then it will take priority for transmission over any packet that will also be available in any of the other queues. A packet in queue 2 will be transmitted only if no packet is available in queue 3. Weighted round robin is an alternative to strict priority scheduling.

4.4.13.2 Weighted Round Robin (WRR) Scheduling
WRR scheduling is an alternative to strict priority scheduling for egress queues. It is referred to as fair queuing because it gives proportionally higher priority to the highest priority queue, but not absolute priority.

4.4.13.3 Rate Limiting
The device supports independent ingress and egress hardware rate limiting on each port. Normally these two features are considered mutually exclusive, and users are discouraged from using both on the same port.

For 10BASE-Te, a rate setting above 10Mbps means the rate is not limited. Likewise, for 100BASE-TX, a rate setting above 100Mbps means the rate is not limited. On the receive side, the data receive rate for each priority at each port can be limited by setting up ingress rate control registers. On the transmit side, the data transmit rate for each priority queue at each port can be limited by setting up egress rate control registers. The size of each frame has options to include minimum inter-frame gap (IFG) or preamble byte, in addition to the data field (from packet DA to FCS). For ingress rate limiting, the device provides options to selectively choose frames from all types, multicast, broadcast, and flooded unicast frames. The data rate from those selected type of frames is counted. Packets are dropped at the ingress port when the data rate exceeds the specified rate limit.

For egress rate limiting, the leaky bucket algorithm is applied to each output priority queue for shaping output traffic. Inter-frame gap is stretched on a per frame base to generate smooth, non-burst egress traffic. The throughput of each output priority queue is limited by the egress rate specified.

If any egress queue receives more traffic than the specified egress rate throughput, packets may be accumulated in the output queue and packet memory. After the memory of the queue or the port is used up, packet dropping or flow control will be triggered. As a result of congestion, the actual egress rate may be dominated by flow control/dropping at the ingress end, and may be therefore slightly less than the specified egress rate.

To reduce congestion, it is a good practice to ensure that the egress bandwidth exceeds the ingress bandwidth.
4.4.14 INGRESS MAC ADDRESS FILTERING FUNCTION

When a packet is received, the destination MAC address is looked up in both the static and dynamic MAC address tables. If the address is not found in either of these tables, then the destination MAC address is “unknown”. By default, an unknown packet is forwarded to all ports except the port at which it was received. An optional feature makes it possible to specify the port or ports to which to forward unknown packets. It is also possible to specify no ports, meaning that unknown packets will be discarded. This feature is implemented separately for unknown unicast, unknown multicast and unknown VID packets.

4.4.15 802.1X ACCESS CONTROL

IEEE 802.1X is a Port-based authentication protocol. EAPOL is the protocol normally used by the authentication process as uncontrolled Port. By receiving and extracting special EAPOL frames, the host processor can control whether the ingress and egress ports should forward packets or not. If a user port wants service from another port (authenticator), it must get approved by the authenticator. The device detects EAPOL frames by checking the destination address of the frame. The destination addresses should be either a multicast address as defined in IEEE 802.1x (01-80-C2-00-00-03) or an address used in the programmable reserved multicast address domain with offset -00-03. Once EAPOL frames are detected, the frames are forwarded to the host port so it can send the frames to the authenticator server. Eventually, the CPU determines whether the requester is qualified or not based on its source MAC address, and frames are either accepted or dropped.

When the device is configured as an authenticator, the ports of the switch must then be configured for authorization. In an authenticator-initiated port authorization, a client is powered up or plugs into the port, and the authenticator port sends an Extensible Authentication Protocol (EAP) PDU to the supplicant requesting the identification of the supplicant. At this point in the process, the port on the switch is connected from a physical standpoint; however, the 802.1X process has not authorized the port and no frames are passed from the port on the supplicant into the switching fabric. If the supplicant attached to the switch (KSZ9897S) did not understand the EAP PDU that it was receiving from the switch, it would not be able to send an ID and the port would remain unauthorized. In this state, the port would be blocked from passing any user traffic. If the supplicant is running the 802.1X EAP, it would respond to the request with its configured ID. (This could be a user name/password combination or a certificate.)

After the device receives the ID from the supplicant, it passes the ID information to an authentication server (RADIUS server) that can verify the identification information. The RADIUS server responds to the switch with either a success or failure message. If the response is a success, the port will be authorized and user traffic will be allowed to pass through the port like any switch port connected to an access device. If the response is a failure, the port will remain unauthorized and, therefore, unused. If there is no response from the server, the port will also remain unauthorized and will not pass any traffic.

Port control can be performed via the Access Control List (ACL) Filtering feature.

4.4.16 ACCESS CONTROL LIST (ACL) FILTERING

An Access Control List (ACL) can be created for each port to perform filtering on incoming layer 2 MAC, layer 3 IP or layer 4 TCP/UDP packets. Multicast filtering is handled in the Static Address Table and the Reserved Multicast Address Table, but the ACL provides additional capabilities for filtering routed network protocols. As shown in Figure 4-3, ACL filtering may take precedence over other forwarding functions.

The ACL allows the switch to filter ingress traffic based on the following header fields:
- Source or destination MAC address and/or EtherType
- Source or destination IPv4 address with programmable mask
- IPv4 protocol
- Source or destination UDP port
- Source or destination TCP port
- TCP Flag with programmable mask

The ACL is implemented as an ordered list of up to 16 access control rules which are programmed into the ACL Table. Each entry specifies certain rules (a set of matching conditions and action rules) to control the forwarding and priority of packets. When a packet is received on an interface, the switch compares the fields in the packet against any applied ACLs to verify that the packet has the permissions required to be forwarded, based on the conditions specified in the lists. Multiple match conditions can be either AND’ed or OR’ed together.
The ACL can also implement a count function that generates an interrupt rather than a forwarding action. The counter can be either a watchdog timer or an event counter. As a watchdog timer, an interrupt is generated if a packet with a specific MAC address and EtherType is not received within a specified time interval. As an event counter, an interrupt is generated once a specified number of packets with a specific MAC address and EtherType have been received.

The ACL consists of three parts: matching rules, action rules, and processing entries. A matching rule specifies what comparison test shall be performed on the incoming packet. It can also enable a counter function. An action rule specifies the forwarding action to be taken if the matching test succeeds. Alternatively, when a count function is enabled in a matching rule, the 11-bit count value is stored in the corresponding action rule field and there is no forwarding action.

In general, the 16 matching rules are not directly linked to the 16 action rules. For example, matching entry #0 is not necessarily related to action entry #0. The exception is when the counter function is enabled in a matching rule, whereby the matching rule and action rule fields at the same ACL table entry will function together and are no longer independent.

Each of the 16 processing entries is used to link any number of matching rules (specified in RuleSet) to any one action rule (specified in FRN). When there are multiple matching rules in a RuleSet, those rules are AND'ed together. Only if all of those matching results are true will the FRN action be taken.

It is also possible to configure the ACL table so that multiple processing entries specify the same action rule. In this way, the final matching result is the OR of the matching results from each of the multiple RuleSets.

The 16 ACL rules represent an ordered list, with entry #0 having the highest priority and entry #15 having the lowest priority. All matching rules are evaluated. If there are multiple true match results and multiple corresponding actions, the highest priority (lowest numbered) of those actions will be the one taken.

4.4.16.1 Processing Entry Description

The Processing Entry consists of two parameters as described in Table 4-15.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| FRN[3:0]      | First Rule Number  
Pointer to a Action rule entry. Possible values are 0 to 15. If all Matching rules specified in the RuleSet are evaluated true, then this is the resulting Action rule. |
| RuleSet[15:0] | Specifies a set of one or more Matching rule entries. RuleSet has one bit for each of the 16 Matching rule entries. If multiple Matching rules are selected, then all conditions will be AND'ed to produce a final match result. 0 = Matching rule not selected 1 = Matching rule selected |
The examples in Figure 4-6 are interpreted as follows:

- Rule #0: Test the matching rule entry #0. If true, apply action rule entry #0.
- Rule #1: Test the matching rule entry #1. If true, apply action rule entry #0.
- Rule #2: Test the matching rule entry #2. If true, apply action rule entry #1.
- Matching rule entry #3 is configured for the counter function. Action entry #3 is used to hold the corresponding count value.
- Rule #4: Test the matching rule entries #4, 5 and 6. If all are true, apply action rule entry #4.
- Rule #6: Test the matching rule entry #6. If true, apply action rule entry #5.
- Rule #8: Test the matching rule entries #7 and 11. If both are true, apply action rule entry #9.

No more than one action can be taken for any packet. If the matching conditions are true for multiple RuleSets, then the corresponding FRN field with the lowest value (highest priority) determines the action to be taken.

Note that processing entries #0 and 1 produce an OR function: action #0 is taken if RuleSet #0 or RuleSet #1 is true.

Notice that processing entries #4 and 6 have overlapping RuleSets, but different FRNs. This can be summarized as:

- If match #4, 5 and 6 are all true, then apply action #4,
- Else if match #6 is true, then apply action #5.
Table 4-16 summarizes the available matching options. The MD and ENB fields are used to select the desired matching option. More configuration details are given in the following section.

4.4.16.2 Matching Rule Description

The Matching Rule consists of several parameters. The first two parameters, MD[1:0] and ENB[1:0], determine the organization of the remainder of each Matching Rule.

When MD = 00, the Matching Rule is disabled.

</tbody>
</table>

Details for MD = 01, ENB = 00:

The 11 bits of the aggregated bit fields from PM, P, RPE, RP and MM in the Action rule entry specify a count value for packets matching MAC Address and TYPE in the Matching Field.
The count unit is determined by the TU bit (located in the Action rule).

- When 0, the unit is microsecond.
- When 1, the unit is millisecond.

The CA bit (located in the Action rule) determines the algorithm used to generate an interrupt when the count terminates.

- When 0, an 11-bit counter will be loaded with the count value from the list and start counting down every unit time. An interrupt will be generated when the timer expires, i.e. the next qualified packet has not been received within the period specified by the value.
- When 1, the counter is incremented with every matched packet received. An interrupt is generated when the terminal count is reached. The count resets thereafter. Time units are not used in this mode.

</table>
Figure 4-7 shows basic organization of the ACL Table. The table has 16 entries, and each entry includes a matching field, action field and process field. Although these fields are stored together in one table, it is important to note that for a given table entry, the Matching, Action and Process fields generally do not form an associated group. The one exception is when the Matching Rule is in Count Mode (MD = 01 and ENB = 00). In that case, the Matching and Action fields are used in tandem.

An interrupt is generated when the terminal count is reached. The count resets thereafter. Time units are not used in this mode.</td>
</tr>
</tbody>
</table>

FIGURE 4-7: ACL TABLE FORMAT

4.4.16.4 ACL Interrupts

The ACL filtering functions do not generate interrupts. Interrupts apply only for the Count Mode (MD = 01, ENB = 00). The Matching Rule can be configured either to timeout if the interval between packets of a specific type (MAC address and EtherType), or when a set number of these packets are received. There is a separate interrupt for each port. Port specific interrupt status and masks are located in the Port Interrupt Status Register and Port Interrupt Mask Register. The top level interrupt registers for each port are in the Global Port Interrupt Status Register and Global Port Interrupt Mask Register.
4.4.16.5 ACL Registers

Table 4-22 provides a list of ACL related registers.

4.5 NAND Tree Support

The KSZ9897S provides parametric NAND tree support for fault detection between chip I/Os and board. The NAND tree is a chain of nested NAND gates in which each KSZ9897S digital I/O (NAND tree input) pin is an input to one NAND gate along the chain. At the end of the chain, the \texttt{INTRP\_N} pin provides the output for the last NAND gate.

The NAND tree test process includes:

- Enabling NAND tree mode
- Pulling all NAND tree input pins high
- Driving low each NAND tree input pin sequentially per the NAND tree pin order, starting with the first row of Table 4-23.
- Checking the NAND tree output to ensure there is a toggle high-to-low or low-to-high for each NAND tree input driven low.

<td>94</td>
<td>INTRP_N</td>
<td>Output</td>
</tr>
</tbody>
</table>
The following procedure can be used to check for faults on the KSZ9897S digital I/O pin connections to the board:

1. Enable NAND tree mode via the LED2_1, LED2_0, and LED4_0 configuration strap pins option.
2. Use board logic to drive all KSZ9897S NAND tree input pins high and verify that the INTRP_N pin output is high.
3. Use board logic to drive each NAND tree input pin, per the NAND Tree pin order, as follows:
   a) Toggle the first pin in the NAND tree sequence (LED4_0) from high to low, and verify the INTRP_N pin switches from high to low to indicate that the first pin is connected properly.
   b) Leave the first pin (LED4_0) low.
   c) Toggle the second pin in the NAND tree sequence (LED4_1) from high to low, and verify the INTRP_N pin switches from low to high to indicate that the second pin is connected properly.
   d) Leave the first pin (LED4_0) and the second pin (LED4_1) low.
   e) Toggle the third pin in the NAND tree sequence (LED3_0) from high to low, and verify the INTRP_N pin switches from high to low to indicate that the third pin is connected properly.
   f) Continue with this sequence until all KSZ9897S NAND tree input pins have been toggled.

Each KSZ9897S NAND tree input pin must cause the INTRP_N output pin to toggle high-to-low or low-to-high to indicate a good connection. If the INTRP_N pin fails to toggle when the KSZ9897S input pin toggles from high to low, the input pin has a fault.

4.6 Clocking

4.6.1 PRIMARY CLOCK

The device requires a 25MHz reference clock input at the XI pin. This clock is internally multiplied up and used to clock all of the internal logic and switching functions. It is also normally used as to clock the PHY transmit paths. This clock may be supplied by connecting a crystal between the XI and XO pins (and appropriate load capacitors to ground). Alternatively, an external CMOS clock signal may drive XI, while XO is left unconnected. The XI/XO block is powered from AVDDH.

4.6.2 PORT 6 RGMII/MII/RMII CLOCKS

The MII interface is clocked asymmetrically, with the PHY device driving both the RX_CLK6 receive clock and the TX_CLK6 transmit clock to the MAC device. The MII port may be configured at reset by a strapping option to take the role of either the PHY or the MAC. RX_CLK6 and TX_CLK6 are therefore either both inputs or both outputs, depending on the MII mode.

The RMII interface uses a single 50MHz clock. This REFCLK may be sourced either from the KSZ9897S or from the connected device. A strapping option is used to select the mode. "Normal Mode" is the mode where the other device supplies the clock, and the clock is an input to the REFCLKI6 pin of the device. "Clock Mode" is the mode where the KSZ9897S generates the 50MHz clock on the REFCLKO6 pin.

The RGMII interface employs source synchronous clocking, so it is symmetrical and does not require a mode selection. An output clock is generated on the RX_CLK6 pin, while an input clock is received on the TX_CLK6 pin. The clock speed scales with the interface data rate - either 10, 100 or 1000 Mbps. A strapping option is used to select between the 100 and 1000 Mbps speeds. If the 10 Mbps rate is required, then a register setting is used to set that speed.

The Port 6 MAC interface is powered from VDDIO.

Note: Refer to Section 3.2.1, "Configuration Straps," on page 16 for additional information on using configuration straps.
4.6.3 PORT 7 SGMII CLOCK
The SGMII interface consists of two differential serial data signals: one transmit pair and one receive pair. No clock is transmitted or received. Each receiver must perform clock and data recovery from the received data signal. The internal SGMII transmit clock is derived from the 25MHz reference clock at $XI$. 

\[Note:\] Refer to Section 3.2.1, "Configuration Straps," on page 16 for additional information on using configuration straps.

4.6.4 SERIAL MANAGEMENT INTERFACE CLOCK
Whether configured to be SPI, I²C or MIIM, the KSZ9897S is always a slave and receives the clock as an input. The serial management interface is powered from $VDDIO$.

4.6.5 CLKO_25_125
An output clock, derived from the local 25MHz reference at $XI$, is provided on the CLKO_25_125 pin. The output frequency choices are 25MHz (default) and 125MHz. If not needed, this output clock can also be disabled. CLKO_25_125 is controlled via the Output Clock Control Register, and is powered from $VDDIO$. 

4.7 Power

The KSZ9897S requires two to three supply voltages. The device core operates from a 1.2V supply (DVDDL and AVDDL). The PHY transceivers and XI/XO crystal/clock interface operate from a 2.5V supply (AVDDH). The digital I/O's can be operated from 1.8V, 2.5V or 3.3V (VDDIO). The digital I/Os powered from VDDIO include RGMII, RMII, MII, SPI, I2C, MIIM, LED, RESET_N, PME_N, INTRP_N and CLKO_25_125. The SGMII interface requires 2.5V (VDDHS) and 1.2V (VDDLS) supplies. An example power connection diagram can be seen in Figure 4-8.

FIGURE 4-8: POWER CONNECTION DIAGRAM
4.8 Power Management

The device supports enhanced power management features in a low-power state with energy detection to ensure low-power dissipation during device idle periods. There are three operation modes under the power management function which are implemented globally (i.e., applying to all ports):

- Normal Operation Mode
- Energy Detect Mode
- Global Soft Power Down Mode

Table 4-24 summarizes all internal function blocks status under the three power-management operation modes.

<table>
<thead>
<tr>
<th>Functional Blocks</th>
<th>Power Management Operation Modes</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>TX/RX PHYs</td>
<td>Enabled</td>
</tr>
<tr>
<td>MACs</td>
<td>Enabled</td>
</tr>
<tr>
<td>Host Interface</td>
<td>Enabled</td>
</tr>
</tbody>
</table>

There is one additional power saving mode that may be implemented on a per-port basis:

- Port-Based Power Down

The first three global power modes are mutually exclusive; only one mode may be selected at a time. Port-based power down may be enabled independent of the global power mode.

4.8.1 NORMAL OPERATION MODE

At power-up, the device enters into Normal operation mode. It is also selected via bits [4:3] = 00 in the Power Down Control 0 Register. When the device is in normal operation mode, all PLL clocks are running, PHYs and MACs are on, and the CPU is ready to read or write the device registers through the serial interface (SPI, I²C or MIIM).

During normal operation mode, the host processor can change the power management mode bits in the Power Down Control 0 Register to transition to any of the other power management modes.

4.8.2 ENERGY-DETECT MODE

Energy-detect mode, also known as energy-detect power down (EDPD) mode, is enabled by setting bits [4:3] to 01 in the Power Down Control 0 Register. Energy-detect mode provides a mechanism to save power when the device is not connected to an active link partner. Auto-negotiation must be enabled when in energy-detect mode.

Energy-detect mode consists of two states, normal-power state and low-power state. When the device is in this mode, it will monitor the cable energy. If there is no energy on the cable for a time longer than a pre-configured value, the device will go into the low-power state. While in low-power state, the device reduces power consumption by disabling all circuitry except the energy-detect circuitry of the receiver, which consumes minimal power. When the device is in the low-power state, it will transmit link pulses at long intervals, with a very low duty cycle. At the same time, it continuously monitors for energy on the cable. Once energy is detected from the cable and is present for a time longer than 100ns, the device will enter the normal-power state.

4.8.3 GLOBAL SOFT POWER-DOWN MODE

Soft power-down mode is used to power down the device when it is not in use after power-up. This mode disables all internal functions except for the serial (SPI or I²C) management interface.

When soft power-down mode is exited, all registers are reset to their default values, and all configuration strap pins are sampled to set the device settings.

4.8.4 PORT-BASED POWER DOWN

Unused ports may be powered down individually to save power.
4.8.5 WAKE ON LAN (WOL)

Wake on LAN allows a computer to be turned on or woken up by a network message. The message is usually sent by a program executed on another computer on the same local area network. Wake-up frame events are used to awaken the system whenever meaningful data is presented to the system over the network. Examples of meaningful data include the reception of a Magic Packet, a management request from a remote administrator, or simply network traffic directly targeted to the local system. The device can be programmed to notify the host of the Wake-Up frame detection with the assertion of the power management event signal (PME_N).

The device’s MACs support the detection of the following Wake-Up events:
- Detection of energy signal over a pre-configured value
- Detection of a linkup in the network link state
- Receipt of a Magic Packet

There are also other types of Wake-Up events that are not listed here as manufacturers may choose to implement these in their own way.

4.8.5.1 Direction of Energy

The energy is detected from the cable and is continuously presented for a time longer than pre-configured value, especially when this energy change may impact the level at which the system should re-enter to the normal power state.

4.8.5.2 Direction of Link-up

Link status wake events are useful to indicate a linkup in the network's connectivity status.

4.8.5.3 Magic Packet™

The Magic Packet is a broadcast frame containing anywhere within its payload 6 bytes of all 1s (FF FF FF FF FF FF) followed by sixteen repetitions of the target computer's 48-bit DA MAC address. Since the magic packet is only scanned for the above string, and not actually parsed by a full protocol stack, it may be sent as any network- and transport-layer protocol.

Magic Packet technology is used to remotely wake up a sleeping or powered-off PC on a LAN. This is accomplished by sending a specific packet of information, called a Magic Packet frame, to a node on the network. When a PC capable of receiving the specific frame goes to sleep, it enables the Magic Packet RX mode in the LAN controller, and when the LAN controller receives a Magic Packet frame, it will alert the system to wake up. Once the device has been enabled for Magic Packet Detection, it scans all incoming frames addressed to the node for a specific data sequence, which indicates to the controller this is a Magic Packet frame.

A Magic Packet frame must also meet the basic requirements for the LAN technology chosen, such as Source Address (SA), Destination Address (DA), which may be the receiving station's IEEE MAC address, or a multicast or broadcast address and CRC. The specific sequence consists of 16 duplications of the MAC address of this node, with no breaks or interruptions. This sequence can be located anywhere within the packet, but must be preceded by a synchronization stream. The synchronization stream is defined as 6 bytes of 0xFF. The device will also accept a broadcast frame, as long as the 16 duplications of the IEEE address match the address of the machine to be awakened.

4.8.5.4 Interrupt Generation on Power Management Related Events

There are two ways an interrupt can be generated to the host whenever a power management related event takes place. The resulting interrupts are via the PME_N signal pin or via the INTRP_N signal pin.

4.9 Management Interface

The management interface may be used by an external host processor to read and write the device's registers. This interface has three available modes of operation: SPI, I²C or MIIM. The interface mode is selected at the deassertion of reset by a strapping option (refer to Section 3.2.1, “Configuration Straps,” on page 16 for additional information).

Of the three interface options, SPI provides the highest performance, while MIIM performance is the lowest. Most importantly, MIIM provides access to the PHY control and status registers, but not to any of the switch registers. The vast majority of applications therefore can use SPI or I²C, but not MIIM.

Register access is also available through the high-performance in-band management interface as described in Section 4.10, “In-Band Management,” on page 57.
4.9.1 SPI SLAVE BUS

The KSZ9897S supports a slave mode SPI interface that provides complete access to all device registers via an SPI master device. The SPI master device supplies the clock (SCL), select (SCS_N), and serial input data (SDI). Serial output data (SDO) is driven by the KSZ9897S.

SCL is expected to stay low when SPI operation is idle. SPI operations start with the falling edge of SCS_N and end with the rising edge of SCS_N. A single read or write access consists of a 27-bit command/address phase, then a 5-bit turn-around (TA) phase, then an 8-bit data phase. For burst read or write access, SCS_N is held low while SCL continues to toggle. For every 8 cycles of SCL, the device will increment the address counter, and the corresponding data byte will be transferred on SDI or SDO in succession.

All commands, addresses and data are transferred most significant bit first. Input data on SDI is latched on the rising edge of clock SCL. Output data on SDO is clocked on the falling edge of SCL.

As shown in Figure 4-25, there are two commands: register read and register write. Figure 4-9 and Figure 4-10 show the timing for these two operations.

### TABLE 4-25: REGISTER ACCESS USING THE SPI INTERFACE

<table>
<thead>
<tr>
<th>SPI Operation</th>
<th>Command/Address Phase (SDI pin)</th>
<th>TA bits (Note 4-8)</th>
<th>Data Phase (SDO or SDI pins)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Register Read</td>
<td>011 A23 A22 A21 A20 ... A7 A6 A5 A4 A3 A2 A1 A0</td>
<td>XXXXX</td>
<td>D7 D6 D5 D4 D3 D2 D1 D0</td>
</tr>
<tr>
<td>Register Write</td>
<td>010 A23 A22 A21 A20 ... A7 A6 A5 A4 A3 A2 A1 A0</td>
<td>XXXXX</td>
<td>D7 D6 D5 D4 D3 D2 D1 D0</td>
</tr>
</tbody>
</table>

**Note 4-8** TA bits are turn-around bits. They are “don’t care” bits.

**Note:** The actual device address space is 16 bits (A15 - A0), so the values of address bits A23 - A16 in the SPI command/address phase are “don’t care”.

### FIGURE 4-9: SPI REGISTER READ OPERATION

### FIGURE 4-10: SPI REGISTER WRITE OPERATION
4.9.2 I²C BUS

The management interface may be configured to be an I²C slave. In this mode, an I²C master has complete programming access to the device's internal control and status registers, including all MIB counters, address lookup tables, VLAN table and ACL table.

The 7-bit device address is fixed as 1011_111. Because of the fixed address, only one KSZ9897S may be on the I²C bus at a time. The R/W control bit is then appended as the least significant bit to form these 8-bit address/control words:

1011_1110 <write>
1011_1111 <read>

The internal registers and tables of the device are accessed using 16-bit addressing and 8-bit data. The access formats are as follows:

FIGURE 4-11: SINGLE BYTE REGISTER WRITE

4.9.3 MII MANAGEMENT (MIIM) INTERFACE

The device supports the IEEE 802.3 MII management interface, also known as the management data input/output (MDIO) interface. This interface allows upper-layer devices to monitor and control the states of the KSZ9897S PHY blocks, but it does not provide access to the switch registers. An external device with MDC/MDIO capability can read the PHY status or configure the PHY settings. Details on the MIIM interface can be found in Clauses 22 and 45 of the IEEE 802.3 Specification.
Use of MIIM conflicts with use of the In-Band Management interface. These interfaces cannot be used simultaneously.

The MIIM interface consists of the following:

- A physical connection that uses a data signal (MDIO) and a clock signal (MDC) for communication between an external controller and the KSZ9897S. Note that the MDIO signal is open-drain.
- A specific protocol that operates across the two signal physical connection that allows an external controller to communicate with the internal PHY devices.
- Access to a set of standard, vendor-specific and extended (MMD) 16-bit registers. These registers are also directly accessible via the SPI and I2C interface options.

The MIIM Interface can operate up to a maximum clock speed of 5MHz. Access is limited to only the registers in the PHY blocks of ports 1 through 5. **Table 4-26** summarizes the MII management interface frame format.

**TABLE 4-26: MII MANAGEMENT INTERFACE FRAME FORMAT**

<table>
<thead>
<tr>
<th>Operation Mode</th>

</tr>
</tbody>
</table>

The MIIM PHY address to PHY port mapping is as follows:

- PHY Address 1h to PHY port 1
- PHY Address 2h to PHY port 2
- PHY Address 3h to PHY port 3
- PHY Address 4h to PHY port 4
- PHY Address 5h to PHY port 5

The MIIM register address space consists of two distinct areas.

- **Standard MIIM Registers (Direct)**
- **MDIO Manageable Device (MMD) Registers (Indirect)**

**4.9.3.1 Standard MIIM Registers (Direct)**

Standard registers provide direct read/write access to a 32-register address space, as defined in Clause 22 of the IEEE 802.3 Specification. Within this address space, the first 16 registers (Registers 0h to Fh) are defined according to the IEEE specification, while the remaining 16 registers (Registers 10h to 1Fh) are defined specific to the PHY vendor.

The KSZ9897S supports the standard registers listed in **Table 4-27** for each PHY port. Each 16-bit MIIM Standard Register Address maps to two corresponding 8-bit Port N Register Addresses. The register bit map and description are located at the 8-bit Port N Register Addresses.

4.9.3.2 MDIO Manageable Device (MMD) Registers (Indirect)

The MIIM interface provides indirect access to a set of MMD registers as defined in Section 5.4, "MDIO Manageable Device (MMD) Registers (Indirect)," on page 169.

4.10 In-Band Management

The in-band management access (IBA) is a feature that provides full register read and write access via any one of the seven data ports. Port 7 is the default IBA port. The in-band feature is enabled or disabled by a strapping option at power-up and reset. To use a different port instead of port 7 for IBA, the SPI or I²C interface or IBA must be used to write to a control register. IBA may not be used on more than one port at a time, but the IBA port can still be used for sending and receiving non-IBA traffic.

In-band management frames are processed differently from normal network frames. They are recognized as special frames, so address and VID lookup, VLAN tagging, source address filtering, un-tag discard, tagged frame drop, etc. are not applied to them. Received in-band management frames are never forwarded to the switch fabric or to any other port.
The In-Band Management (IBA) Control Register is used to enable and control the IBA feature and to specify one of the seven ports as the IBA port.

The IBA frame format is shown in Figure 4-15. The layer 2 portion of the IBA frame contains normal destination address (DA) and source address (SA) fields. The DA of the frames are defined to be the switch MAC address (default 00-10-A1-FF-FF-FF), and the SA is the MAC address of the source device. The DA and SA will be swapped in the response frame. A special 4-byte IBA tag follows the SA. This is then followed by the 2-byte EtherType/Length field that serves to identify this as an IBA frame.

Only one IBA frame can be processed at a time. Any subsequent IBA frames received by the device will be dropped unless the most recent response frame has been fully transmitted.

There are six types of read/write commands: READ, WRITE, WAIT on 0, WAIT on 1, MODIFY to 0 and MODIFY to 1. The minimum IBA read or write size is 32 bits. There is no IBA option for 8-bit or 16-bit transfers.

The burst commands offer fast and bundled data return, up to the capacity of the IBA frame buffer. There are two types of operations in burst command: READ bust and Write bust.

**FIGURE 4-15: IN-BAND MANAGEMENT FRAME FORMAT**
4.11 MAC Interface (Ports 6 and 7)

Strapping options are used to individually select any of these MAC interface options for port 6:
- **Media Independent Interface (MII) (Port 6):** Supports 100 and 10 Mbps data rates
- **Reduced Media Independent Interface (RMII) (Port 6):** Supports 100 and 10 Mbps data rates
- **Reduced Gigabit Media Independent Interface (RGMII) (Port 6):** Supports 1000, 100 and 10 Mbps data rates

Port 7 is permanently configured as an SGMII port:
- **Serial Gigabit Media Independent Interface (SGMII) (Port 7):** Supports 1000, 100 and 10 Mbps data rates

Note that the signals on the KSZ9897S MAC interfaces are named as they would be for a PHY: the TX direction is into the KSZ9897S, while the RX direction is out of the KSZ9897S, as if to a host processor with integrated MAC. Signal connection to such a “MAC” device is TX-to-TX, and RX-to-RX.

An external PHY (such as the Microchip KSZ9031RNX) may be connected to port 6, but in that case the signal connection will be RX-to-TX, and TX-to-RX.

The Port 6 MII/RMII/RGMII interface is powered by the VDDIO power supply.

4.11.1 MEDIA INDEPENDENT INTERFACE (MII) (PORT 6)

The media independent interface (MII) is specified in Clause 22 of the IEEE 802.3 standard. It provides a common interface between PHY layer and MAC layer devices. The data interface is 4-bits wide and runs at one quarter the network bit rate; either 2.5MHz in 10BASE-Te or 25MHz in 100BASE-TX (not encoded). Additional signals on the transmit side indicate when data is valid or when an error occurs during transmission. Similarly, the receive side provides signals that convey when the data is valid and without physical layer errors. For half duplex operation, the COL signal indicates if a collision has occurred during transmission.

The MII interface operates in either PHY Mode or MAC Mode. Select PHY Mode when the port is connected to a processor or other device with a MAC function; select MAC Mode when connecting to an external PHY. Note that the direction of the TX_CLK6, RX_CLK6, COL6 and CRS6 signals is affected by the PHY mode or MAC mode setting, while other MII signals do not change direction.

MII mode is selected at reset by a configuration strap option on pins RXD6_3 and RXD6_2 for port 6. The Speed strapping option (on pin RXD6_0 for port 6) should be set for 100/10 Mbps Mode. PHY Mode or MAC Mode is selected by a configuration strap option on pin RXD6_1 (port 6). Refer to Section 3.2.1, "Configuration Straps," on page 16 for additional information.

The interface contains two distinct groups of signals, one for transmission and the other for reception. Table 4-28 and Table 4-29 describe the signals used by the MII interface to connect to an external MAC or to an external PHY, respectively.

4.11.2 REDUCED MEDIA INDEPENDENT INTERFACE (RMII) (PORT 6)

The reduced media independent interface (RMII) specifies a low pin count interface, which is based on MII, that provides communication with a MAC attached to the port. As with MII, RMII provides a common interface between physical layer and MAC layer devices, or between two MAC layer devices, and has the following key characteristics:

- Supports network data rates of either 10Mbps or 100Mbps.
- Uses a single 50MHz clock reference (provided internally or externally) for both transmit and receive data.
- Uses independent 2-bit wide transmit and receive data paths.
- Contains two distinct groups of signals: one for transmission and the other for reception.

The user selects one of the two RMII clocking modes by setting the appropriate strapping option.

While in RMII Normal Mode, the port will require an external 50MHz signal to be input to TX_CLK6/REFCLKI6 from an external source. This mode is selected by strapping the RXD6_1 pin high during reset.

While in RMII Clock Mode, the port will output a 50MHz clock on RX_CLK6/REFCLKO6, which is derived from the 25MHz crystal or oscillator attached to the XI clock input. The TX_CLK6/REFCLKI6 input is unused in this mode. This mode is selected by strapping the RXD6_1 pin low during reset.

Refer to Section 3.2.1, "Configuration Straps," on page 16 for additional configuration strap information.

Table 4-30 describes the signals used by the RMII interface. Refer to the RMII specification for full details on the signal descriptions.

A device port in RMII mode may connect to either an external MAC device (such as a host processor) or to an external PHY; but unlike MII, RMII does not provide separate PHY and MAC modes of operation. However, it is necessary to connect the pins properly.

#### 4.11.3 REDUCED GIGABIT MEDIA INDEPENDENT INTERFACE (RGMII) (PORT 6)

RGMII provides a common interface between RGMII PHYs and MACs, and has the following key characteristics:

- Pin count is reduced from 24 pins for GMII to 12 pins for RGMII.
- All speeds (10Mbps, 100Mbps and 1000Mbps) are supported at both half- and full-duplex.
- Data transmission and reception are independent and belong to separate signal groups.
- Transmit data and receive data are each four bits wide - a nibble.

In RGMII operation, the RGMII pins function as follows:

- The MAC sources the transmit reference clock, **TX_CLK6**, at 125MHz for 1000Mbps, 25MHz for 100Mbps, and 2.5MHz for 10Mbps.
- The PHY recovers and sources the receive reference clock, **RX_CLK6**, at 125MHz for 1000Mbps, 25MHz for 100Mbps, and 2.5MHz for 10Mbps.
- For 1000BASE-T, the transmit data, **TXD6 [3:0]**, is presented on both edges of **TX_CLK6**, and the received data, **RXD6 [3:0]**, is clocked out on both edges of the recovered 125MHz clock, **RX_CLK6**.
- For 10BASE-T/100BASE-TX, the MAC holds **TX_CLK6** low until both the PHY and MAC operate at the same speed. During the speed transition, the receive clock is stretched on either a positive or negative pulse to ensure that no clock glitch is presented to the MAC.
- **TX_ER6** and **RX_ER6** are combined with **TX_EN6** and **RX_DV6**, respectively, to form **TX_CTL6** and **RX_CTL6**. These two RGMII control signals are valid at the falling clock edge.

After power-up or reset, the device is configured to RGMII mode if the appropriate configuration strap pins are set to one of the RGMII mode capability options. Refer to **Section 3.2.1, "Configuration Straps," on page 16** for available options. Note that there is no mechanism for the RGMII interface to adapt its speed automatically to the speed of the connected RGMII device. A configuration strap option sets the speed of the RGMII interface at power-up to either 1000Mbps or 100Mbps. A control register can override the configuration strap option and set the RGMII speed to either 1000, 100 or 10Mbps. If a PHY is connected to the RGMII port, it should be ensured that the PHY link speed is fixed in order to avoid a mismatch to the RGMII speed.
The device provides the option to add a minimum of 1.5ns internal delay to either TX_CLK6 or RX_CLK6, via the RGMII Internal Delay control bits in the XMII Port Control 1 Register. This can reduce or eliminate the need to add trace delay to the clock signals on the printed circuit board. RGMII_ID_ig enables delay on TX_CLK6, and the default is off. RGMII_ID_eg enables delay on RX_CLK6, and the default is on. Users should also be aware of any internal clock delay that may be added by the connected RGMII device.

4.11.4 SERIAL GIGABIT MEDIA INDEPENDENT INTERFACE (SGMII) (PORT 7)

The port 7 MAC has a Serial Gigabit Media Independent Interface (SGMII) for interfacing to an external 10/100/1000 BASE-T PHY that supports the SGMII MAC/PHY interface, or to another device with an SGMII interface. This interface also has a SerDes mode for interfacing to 1000BASE-X fiber optic modules or to other modules such as 1000BASE-T which do not support SGMII.

The interface has one receive differential pair and one transmit differential pair for sending and receiving data and control at a serial bit rate of 1.25 Gbaud. The SGMII block recovers the clock from the incoming data. Therefore, a separate input SGMII clock is not needed. Likewise, no output SGMII clock is provided, with the expectation that the connected device will also recover the clock from the receive data.

SGMII uses auto-negotiation to establish the MAC - PHY connection. The PHY-side device is sometimes referred to as the master, and the MAC-side device is referred to as the slave. The PHY-side device relays the following information about the 10/100/1000 BASE-T link to the MAC-side device:

- Speed
- Duplex
- Link up/down status

The switch’s SGMII interface defaults to MAC-side mode, with auto-negotiation enabled. The mode can be changed to PHY-side for connection to a MAC-side device. There is also the option to disable auto-negotiation. If auto-negotiation is disabled, it must also be disabled in both devices. Do not confuse “auto-negotiation” across the SGMII interface with auto-negotiation performed between the PHY and its far-end link partner. When the SGMII speed and duplex can be fixed, as when connected to another switch or a processor, auto-negotiation is optional.

10/100/1000 BASE-T PHYs with SGMII interfaces may be discrete devices or may be housed in SFP modules. Note, however, that not all SFP modules support SGMII.

In SerDes mode, this port uses 1000BASE-X “auto-negotiation”. Unlike the SGMII interface where one device acts as a PHY and one acts as a MAC, the SerDes interface is symmetrical between the two connected devices. Besides being compatible with 1000BASE-X fiber modules, it can also interface to a copper 1000BASE-T PHY or module that uses 1000BASE-X auto-negotiation instead of SGMII, and is fixed at 1 Gbps and full duplex. When a PHY is connected to this port, the auto-negotiation is between the switch and the PHY, and this local PHY is known as the link partner. When a 1000BASE-X fiber module is connected to this port, the auto-negotiation is between the PHY and the distant link partner. The fiber module does not participate in the auto-negotiation.
The switch cannot auto-detect the type of SFP module it is attached to, but a management processor can access the SGMII registers and determine whether the received auto-negotiation codeword corresponds to an SGMII device or a SerDes mode device.

AC coupling should be used on the SGMII differential pairs. AC coupling capacitors are included in SFP modules. The SGMII port has internal termination resistors, which eliminates the need for external termination.

SGMII registers are accessed indirectly via the Port SGMII Address Register and Port SGMII Data Register. Additional information on SGMII registers is provided in Section 5.5, "SGMII Registers (Indirect)," on page 171.

Additional information about this interface and its use is provided in an application note.
5.0 DEVICE REGISTERS

The KSZ9897S has a rich set of registers for device management. The registers are accessed by the SPI or I²C interfaces, or by in-band management. Alternatively, the MIIM interface can be used to access the PHY registers only. The MIIM interface cannot access the switch registers.

A 16-bit address is used to access the device registers. This address is split into three hierarchical spaces, as shown in Figure 5-1. These three spaces are used to designate the port/channel (4-bits), function (page) of the port (4-bits), and register of function (8-bits). The individual ports are numbered 1 through 7. In the port space, a value of 0 is used for global registers. Address bit 15 is always 0.

FIGURE 5-1: REGISTER ADDRESS MAPPING
Register addressing is by bytes, and the management interface (SPI, I²C or in-band) transfers data by bytes. Where registers are shown as 16-bits or 32-bits, this is for descriptive purposes only. Data can always be written and read as individual bytes and in any order.

For multi-byte registers, the data is addressed in a big-endian format, with the most significant byte at the lowest address, and the least significant byte at the highest address, as shown in Figure 5-2.

FIGURE 5-2: BYTE ORDERING

The global and port register address maps are detailed in Table 5-1 and Table 5-2, respectively. Table 1-3, “Register Nomenclature,” on page 7 provides a list of register bit type notations.

The remainder of this chapter is organized as follows:

- Global Registers
- Port Registers
- Tables and MIB Counters (Access)
- MDIO Manageable Device (MMD) Registers (Indirect)
- SGMII Registers (Indirect)

**Note:** RESERVED address space must not be written under any circumstances. Failure to heed this warning may result in untoward operation and unexpected results. If it is necessary to write to registers which contain both writable and reserved bits in the same register, the user should first read back the reserved bits (RO or R/W), “OR” the desired settable bits with the value read, and then write back the “ORed” value to the register.
5.1 Global Registers

This section details the device's global registers. For an overview of the device's entire register map, refer to Section 5.0, "Device Registers". For details on the device's port registers, refer to Section 5.2, "Port Registers".

5.1.1 GLOBAL OPERATION CONTROL REGISTERS (0x0000 - 0x00FF)

5.1.1.1 Global Chip ID 0 Register

Address: 0x0000 Size: 8 bits

<table>
<thead>

</tr>
</tbody>
</table>

  When enabled, this feature automatically determines the edge of SCL that is used to clock out the SPI data on SDO.

  If SCL ≥ ~25MHz, SDO data is clocked by the rising edge of SCL.

  If SCL < ~25 MHz, SDO data is clocked by the falling edge of SCL.

  0 = The automatic feature is disabled, and bit 0 determines the SCL clock edge used for SDO.

  1 = The automatic feature is enabled, and bit 0 is ignored.

<table>
<thead>
<tr>

</table>

### 5.1.4.5 Switch MAC Address 3 Register

Address: 0x0305  Size: 8 bits

<table>
<thead>
<tr>
<th>Bits</th>
<th>Description</th>
<th>Type</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>7:0</td>
<td>MAC Address [23:16]</td>
<td>R/W</td>
<td>0xFF</td>
</tr>
</tbody>
</table>

### 5.1.4.6 Switch MAC Address 4 Register

Address: 0x0306  Size: 8 bits

<table>
<thead>
<tr>
<th>Bits</th>
<th>Description</th>
<th>Type</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>7:0</td>
<td>MAC Address [15:8]</td>
<td>R/W</td>
<td>0xFF</td>
</tr>
</tbody>
</table>

### 5.1.4.7 Switch MAC Address 5 Register

Address: 0x0307  Size: 8 bits

<table>
<thead>
<tr>
<th>Bits</th>
<th>Description</th>
<th>Type</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>7:0</td>
<td>MAC Address [7:0]</td>
<td>R/W</td>
<td>0xFF</td>
</tr>
</tbody>

### 5.1.4.8 Switch Maximum Transmit Unit Register

Address: 0x0308 - 0x0309  Size: 16 bits

<table>
<thead>
<tr>
<th>Bits</th>
<th>Description</th>
<th>Type</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>15:14</td>
<td>RESERVE</td>
<td>R/W</td>
<td>00b</td>
</tr>
<tr>
<td>13:0</td>
<td>Maximum Frame Length (MTU)</td>
<td>R/W</td>
<td>0x07D0</td>
</tr>
</tbody>
</table>

 Specifies the maximum transmission unit (MTU), which is the maximum frame payload size. Frames which exceed this maximum are truncated. This value can be set as high as 9000 (= 0x2328) if jumbo frame support is required. Also refer to the Switch MAC Control 1 Register and Port MAC Control 0 Register.

### 5.1.4.9 Switch ISP TPID Register

Address: 0x030A - 0x030B  Size: 16 bits

<table>
<thead>
<tr>
<th>Bits</th>
<th>Description</th>
<th>Type</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>15:0</td>
<td>ISP Tag TPID</td>
<td>R/W</td>
<td>0x9100</td>
</tr>
</tbody>
</table>

 Default tag TPID (EtherType) for untagged incoming frames or the ISP frame tag TPID for the double tagging function.

### 5.1.4.10 Switch Lookup Engine Control 0 Register

Address: 0x0310  Size: 8 bits

<table>
<thead>
<tr>
<th>Bits</th>
<th>Description</th>
<th>Type</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>7</td>
<td>802.1Q VLAN Enable</td>
<td>R/W</td>

<td>R/W</td>
<td>1b</td>
</tr>
<tr>
<td>5:3</td>
<td>Age Count</td>
<td>R/W</td>
<td>10_0b</td>
</tr>
</tbody>
</table>

- **802.1Q VLAN Enable**: This is the master enable for VLAN forwarding and filtering. Note that the VLAN Table must be set up before VLAN mode is enabled.
  - 1 = VLAN mode enabled
  - 0 = VLAN mode disabled

- **Drop Invalid VID**: All received packets with invalid VLAN ID are dropped.
  - 1 = Received packets with invalid VLAN ID are forwarded to the host port.
  - 0 = Received packets with invalid VLAN ID are dropped.

- **Age Count**: This bit, in combination with the Age Period value (Switch Lookup Engine Control 3 Register), determines the aging time of dynamic entries in the address lookup table. This value is used for the Age Count field whenever a dynamic table entry is updated.
### 5.1.4.11 Switch Lookup Engine Control 1 Register

5.1.4.19 Unknown Unicast Control Register

Address: 0x0320 - 0x0323 Size: 32 bits

The following three registers control forwarding of packets with 1) unknown unicast destination address, 2) unknown multicast destination address, and 3) unknown VLAN ID.

If a received packet falls into more than one of these categories, the precedence is:
1. Unknown VID
2. Unknown Unicast
3. Unknown Multicast

</tbody>
</table>

Note: Refer to Section 5.3.4, "VLAN Table," on page 164 for additional information on VLAN tables.

5.1.5.6 ALU Table Index 0 Register

Address: 0x0410 - 0x0413 Size: 32 bits

The ALU Table Index 0 Register and ALU Table Index 1 Register contain the index values for searching and reading/writing the address lookup table as specified by the action in the ALU Table Access Control Register. For additional information on ALU tables, refer to Section 5.3.1, "Address Lookup (ALU) Table," on page 157.

<table>

</tr>
</tbody>
</table>

5.1.5.8 ALU Table Access Control Register

Address: 0x0418 - 0x041B Size: 32 bits

This register provides control and status for searching and reading or writing the ALU Table. The ALU Table Index 0 Register and ALU Table Index 1 Register contain the index values, while the ALU / Static Address Table Entry 1 Register, ALU / Static Address / Reserved Multicast Table Entry 2 Register, ALU / Static Address Table Entry 3 Register, and ALU / Static Address Table Entry 4 Register are used for the entry values. Refer to Section 5.3.1, "Address Lookup (ALU) Table," on page 157 for additional information on ALU tables.

5.1.5.9 Static Address and Reserved Multicast Table Control Register

This register provides control and index for reading and writing the Static Address Table and the Reserved Multicast Table. The ALU / Static Address Table Entry 1 Register, ALU / Static Address / Reserved Multicast Table Entry 2 Register, ALU / Static Address Table Entry 3 Register, and ALU / Static Address Table Entry 4 Register are used for the Static Address Table entry values, while only the ALU / Static Address / Reserved Multicast Table Entry 2 Register is used for the Reserved Multicast Table entry value. Refer to Section 5.3.2, "Static Address Table," on page 161 and Section 5.3.3, "Reserved Multicast Address Table," on page 163 for additional information on these tables.

</tbody>
</table>
5.1.5.10 ALU / Static Address Table Entry 1 Register

Address: 0x0420 - 0x0423 Size: 32 bits

This register contains the table entry values for read and write operations to the Address Lookup Table and Static Address Table. The field definitions of this register differ dependent on the table type used, as defined in the following sections:

- ALU Table Entry 1 Register on page 160
- Static Address Table Entry 1 Register on page 162

Refer to Section 5.3.1, "Address Lookup (ALU) Table," on page 157 and Section 5.3.2, "Static Address Table," on page 161 for additional information.

5.1.5.11 ALU / Static Address / Reserved Multicast Table Entry 2 Register

Address: 0x0424 - 0x0427 Size: 32 bits

The field definitions of this register differ dependent on the table type used, as defined in the following sections:

- ALU Table Entry 2 Register on page 160
- Static Address Table Entry 2 Register on page 162
- Reserved Multicast Address Table Entry 2 Register on page 164

Refer to Section 5.3.1, "Address Lookup (ALU) Table," on page 157, Section 5.3.2, "Static Address Table," on page 161, and Section 5.3.3, "Reserved Multicast Address Table," on page 163 for additional information.

5.1.5.12 ALU / Static Address Table Entry 3 Register

Address: 0x0428 - 0x042B Size: 32 bits

The field definitions of this register differ dependent on the table type used, as defined in the following sections:

- ALU Table Entry 3 Register on page 161
- Static Address Table Entry 3 Register on page 163

Refer to Section 5.3.1, "Address Lookup (ALU) Table," on page 157 and Section 5.3.2, "Static Address Table," on page 161 for additional information.

5.1.5.13 ALU / Static Address Table Entry 4 Register

Address: 0x042C - 0x042F Size: 32 bits

This register contains the table entry values for read and write operations to the Address Lookup Table and Static Address Table. The field definitions of this register differ dependent on the table type used, as defined in the following sections:

- ALU Table Entry 4 Register on page 161
- Static Address Table Entry 4 Register on page 163

Refer to Section 5.3.1, "Address Lookup (ALU) Table," on page 157 and Section 5.3.2, "Static Address Table," on page 161 for additional information.
### 5.2 Port Registers

This section details the device’s port registers. All settings are on a per-port basis. Address field “N” specifies the port number. Valid values for “N” are 1 to 7 for some registers, 6 to 7 for MAC port specific registers, and 0 to 5 for PHY specific registers.

For an overview of the device’s entire register map, refer to Section 5.0, "Device Registers". For details on the device’s global registers, refer to Section 5.1, "Global Registers".

5.2.3 PORT N: PORT SGMII CONTROL REGISTERS (0xN200 - 0xN2FF)

The Port 7 SGMII registers are accessed indirectly using the following two registers. The indirect SGMII registers, along with details on how to access them, are described in Section 5.5, "SGMII Registers (Indirect)," on page 171.

Steps for SGMII register reads:
1. Write the SGMII register address to the Port SGMII Address Register.
2. Read the SGMII register data from the Port SGMII Data Register.

Steps for SGMII register write:
1. Write the SGMII register address to the Port SGMII Address Register.
2. Write the SGMII register data to the Port SGMII Data Register.

Note: The Port SGMII Address Register must be written as one continuous 32-bit write, and the Port SGMII Data Register must be written as one continuous 16-bit write. These registers may not function correctly if written as multiple 8-bit writes.

5.2.3.1 Port SGMII Address Register

5.2.6 PORT N: PORT SWITCH MIB COUNTERS REGISTERS (0xN500 - 0xN5FF)

Thirty MIB counters are provided for each port. They are accessed via the following two indirect registers. MIB Counters are read-clear. Refer to Section 5.3.6, "Management Information Base (MIB) Counters" for additional details.

**Note:** The Switch MIB Control Register contains two additional bits for global control of MIB counters.

5.2.6.1 Port MIB Control and Status Register

### 5.2.8.3 Port Ingress MAC Control Register

Address: 0xN802  
Port N: 1-7  
Size: 8 bits

<table>
<thead>
<tr>
<th>Bits</th>
<th>Description</th>
<th>Type</th>
<th>Default</th>
</tr>
</thead>
</table>
| 3 | VLAN Priority Classification  
1 = Enable VLAN priority classification for ingress packets on port  
0 = Disabled VLAN classification | R/W | 0b |
| 2 | 802.1p Priority Classification  
1 = Enable 802.1p priority classification for ingress packets on port  
0 = Disable 802.1p priority classification | R/W | 0b |
| 1 | Diffserv Priority Classification  
1 = Enable Diffserv priority classification for ingress packets on port  
0 = Disable Diffserv priority classification | R/W | 0b |
| 0 | ACL Priority Classification  
1 = Enable ACL priority classification for ingress packets on port  
0 = Disable ACL priority classification | R/W | 0b |

#### Bits Description

7 | User Priority Ceiling  
1 = If a packet’s “user priority field” is greater than the “user priority field” in the port default tag register, replace the packet’s user priority field with the user priority field in the port default tag from the Port Default Tag 0 Register.  
0 = Do not replace the user priority field at this port. | R/W | 0b |

6:5 | RESERVED | RO | 0b |

4 | Discard Untagged Packets  
This bit should be left as 0 for the host port.  
1 = Any ingress packet at this port without an IEEE 802.1Q tag is discarded.  
0 = Do not discard. | R/W | 0b |

3 | Discard Tagged Packets  
1 = Any ingress packet at this port with an IEEE 802.1Q tag is discarded.  
0 = Do not discard. | R/W | 0b |

2:0 | Port Default Priority Classification  
If Diffserv classification, 802.1p classification and VLAN classification are not enabled or fail to classify, ingress packets at this port will be classified with the priority specified here. Possible values are 0 to 7. | R/W | 000b |

5.3 Tables and MIB Counters (Access)

Indirect address and data registers are used to access the various tables and counters:

- Address Lookup (ALU) Table
- Static Address Table
- Reserved Multicast Address Table
- VLAN Table
- Access Control List (ACL) Table
- Management Information Base (MIB) Counters

5.3.1 ADDRESS LOOKUP (ALU) TABLE

The Address Lookup Table is the largest of three tables used for MAC address lookup. It supports both dynamic and static MAC address entries. In response to a destination address (DA) lookup, all tables are searched to make a packet forwarding decision. In response to a source address (SA) lookup, only this table is searched for aging, migration and learning of the dynamic entries.

It is suggested that static address entries be programmed to the Static Address Table. When that table is full, additional static address entries may be programmed into this table. Static entries will not be aged out.

A static DA lookup result (in either this table or the Static Address Table) takes precedence over the dynamic DA lookup result.

This table is a 4-way associative memory, with 1K buckets, for a total of 4K entries. In normal operation, the MAC address (and optionally the FID) are hashed to generate a 10-bit index. The 10-bit index specifies a bucket of up to 4 entries, but the entries within each bucket are not individually addressable. A new entry can be added to a bucket if the bucket contains 3 or fewer valid entries. Once a bucket is full with 4 valid entries, any new entry will overwrite the least-recently-used dynamic entry.

If a bucket contains 2 or 3 static entries, adding an additional static entry to that bucket will generate an Almost Full interrupt. (Refer to the Address Lookup Table Interrupt Register and Global Interrupt Status Register). Once the interrupt is generated, the 12-bit absolute address of the new static entry will be available for reading in the Address Lookup Table Entry Index 0 Register bits [11:0].

If a bucket is full with 4 static entries, attempting to write an additional static entry will fail and will result in a Write Fail Interrupt. Once the interrupt is generated, the 10-bit index of the full bucket will be available for reading in the Address Lookup Table Entry Index 0 Register bits [9:0].

A bucket with 4 static entries will also block any dynamic entries from being learned. Such a failure will generate a Learn Fail Interrupt. Once the interrupt is generated, the 10-bit index of the full bucket will be available for reading in the Address Lookup Table Entry Index 1 Register bits [9:0].

This table is accessed indirectly via the ALU Table registers:

- ALU Table Index 0 Register
- ALU Table Index 1 Register
- ALU Table Access Control Register
- ALU Table Entry 1 Register
- ALU Table Entry 2 Register
- ALU Table Entry 3 Register
- ALU Table Entry 4 Register

All static and dynamic entries may be read, but only static entries may be written. Because most of the table entries are created automatically by hardware address learning, and because the table is 4-way associative, three different methods are available for accessing the memory:

1. Lookup by MAC address. This utilizes the same hash tag lookup circuitry that is used for ingress packet forwarding lookup. The hash tag algorithm is specified by the Hash Option bits in the Switch Lookup Engine Control 0 Register. This is normally how static entries should be written (Read or write).
2. Direct addressing (Read or write).
3. Sequential search, returning all valid entries (Read only).
5.3.1.1 Address Lookup Table Read Operation

1. Write the index to the ALU Table Index 0 Register and ALU Table Index 1 Register.
   a) A MAC address is used for the hashing indexing function, which is the normal access mechanism for this table.
   b) A FID is also required if VLAN is enabled.
   c) If directly addressing the table, a 12-bit index is written to bits [11:0] of the MAC address field.

2. Write to the ALU Table Access Control Register.
   a) Set the ACTION field to 10 to indicate a read operation.
   b) Select the addressing method via the DIRECT bit.
   c) Set the START_FINISH bit to initiate the operation.

3. Read / poll the ALU Table Access Control Register.
   a) The START_FINISH bit transitions to 0 to indicate that the operation is complete.
   b) Once START_FINISH is 0, the VALID bit indicates whether or not a valid entry was found. If VALID is false, there is no need to proceed to step 4.
   c) The VALID_ENTRY_OR_SEARCH_END bit is an aggregate of the START_FINISH bit and the VALID bit. It is intended for use when accessing registers by in-band management (IBA), where polling multiple bits is less practical.

4. Read the contents of the returned table entry from the ALU Table Entry 1 Register, ALU Table Entry 2 Register, ALU Table Entry 3 Register, and ALU Table Entry 4 Register. If no VALID entry is returned, these registers will contain all zeros.
5.3.1.2 Address Lookup Table Search Operation

The second method to access the Address Lookup Table is through the search operation. The entire table is searched sequentially, revealing each valid entry. Invalid address entries are skipped, providing an efficient way to search the entire table. Setting the START_FINISH bit in the ALU Table Access Control Register begins the search from the top of the table. This bit is cleared when the search is complete. During the table search, the VALID bit in the ALU Table Access Control Register is cleared when the search starts. The VALID bit indicates when a found valid entry is available in the ALU Table Entry registers (0x0420 - 0x042F). After reading the last ALU Table Entry register (ALU Table Entry 4 Register), the search process automatically continues to seek the next valid entry in the address table. The START_FINISH bit remains set until all the valid entries in the table have been returned. The search can be stopped any time by setting the ALU Table Access Control Register START_FINISH bit to 0.

1. Write to the ALU Table Access Control Register.
   a) Set the ACTION field to 11 to indicate a search operation.
   b) Set the START_FINISH bit to initiate the operation.
2. Poll the VALID bit until it is set.
   a) If register access is by in-band management (IBA) rather than SPI or I2C, poll VALID_ENTRY_OR_SEARCH_END instead. This bit goes high to indicate either a new valid entry is returned or the search is complete.
3. Read the entry from the ALU Table Entry 1 Register, ALU Table Entry 2 Register, ALU Table Entry 3 Register, and ALU Table Entry 4 Register, in that order.
   a) If the search has ended and there are no more valid entries to read, these registers will return all zeros. In this case, go to step 5.
4. If START_FINISH = 0, go to step 5; else go to step 2.
5. Read VALID_COUNT to verify the number of valid entries.

5.3.1.3 Address Lookup Table Write Operation

1. Perform a read operation to get the contents of the current entry. The values are kept in the ALU Table Entry 1 Register, ALU Table Entry 2 Register, ALU Table Entry 3 Register, and ALU Table Entry 4 Register.
2. Modify the correct entry as necessary. Set the STATIC bit so that the entry is not aged out.
3. Write to the ALU Table Access Control Register.
   a) Set the ACTION field to 01 to indicate a write operation.
   b) Select the addressing method via the DIRECT bit.
   c) Set the START_FINISH bit to initiate the operation.
### 5.3.1.4 ALU Table Entry 1 Register

Address: 0x0420 - 0x0423  
Size: 32 bits

<td>31:0</td>
<td>MAC Address [31:0]</td>
<td>R/W</td>
<td>0x00000000</td>
</tr>
</tbody>
</table>

5.3.2 STATIC ADDRESS TABLE

The Static Address Table is one of three tables used for MAC address lookup. It can hold up to 16 static address entries, thereby minimizing the number of static entries that may need to be programmed into the Address Lookup Table, which is used primarily for dynamic entries. In response to a destination address (DA) lookup, all tables are searched to make a packet forwarding decision. Entries in this table are programmed by the host processor, and are never aged.

A static DA lookup result (in either this table or the Address Lookup Table) takes precedence over the dynamic DA lookup result.

The Static Address Table has 16 entries and is accessed indirectly. The Static Address and Reserved Multicast Table Control Register is used for indexing and read/write control. The following registers are used for the data fields:

- Static Address Table Entry 1 Register
- Static Address Table Entry 2 Register
- Static Address Table Entry 3 Register
- Static Address Table Entry 4 Register

5.3.2.1 Static Address Table Write Operation

1. Write the content of the table entry to the Static Address Table Entry 1 Register, Static Address Table Entry 2 Register, Static Address Table Entry 3 Register, and Static Address Table Entry 4 Register.
2. Write to the Static Address and Reserved Multicast Table Control Register.
   a) Write the TABLE_INDEX field with the 4-bit index value.
   b) Set the TABLE_SELECT bit to 0 to select the Static Address Table.
   c) Set the ACTION bit to 0 to indicate a write operation.
   d) Set the START_FINISH bit to 1 to initiate the operation.
3. When the operation is complete, the START_FINISH bit will be cleared automatically.

5.3.2.2 Static Address Table Read Operation

1. Write to the Static Address and Reserved Multicast Table Control Register.
   a) Write the TABLE_INDEX field with the 4-bit index value.
   b) Set the TABLE_SELECT bit to 0 to select the Static Address Table.
c) Set the ACTION bit to 1 to indicate a read operation.

d) Set the START_FINISH bit to 1 to initiate the operation.

When the operation is complete, the START_FINISH bit will be cleared automatically.

a) Read the contents of the indexed entry from the Static Address Table Entry 1 Register, Static Address Table Entry 2 Register, Static Address Table Entry 3 Register, and Static Address Table Entry 4 Register.

### 5.3.2.3 Static Address Table Entry 1 Register

Address: 0x0420 - 0x0423  Size: 32 bits

<table>
<thead>
<tr>
<th>Bits</th>
<th>Description</th>
<th>Type</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>

<td>R/W</td>
<td>000_0000b</td>
</tr>
<tr>
<td>15:0</td>
<td>MAC Address [47:32]</td>
<td>R/W</td>
<td>0x0000</td>
</tr>
</tbody>
</table>

5.3.2.6  Static Address Table Entry 4 Register

Address: 0x042C - 0x042F  Size: 32 bits

<table>
<thead>
<tr>
<th>Bits</th>
<th>Description</th>
<th>Type</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>31:0</td>
<td>MAC Address [31:0]</td>
<td>R/W</td>
<td>0x00000000</td>
</tr>
</tbody>
</table>

5.3.3  RESERVED MULTICAST ADDRESS TABLE

The Reserved Multicast Address Table determines the forwarding ports for 48 specific multicast addresses. The table is addressed by the least significant 6 bits of the multicast address, and the table contents are the bits (the PORT_FORWARD field) that represent each possible forwarding port of the device. It is not addressed by the group number in the first column of Table 4-6. Note that the 48 addresses are organized into 8 fixed groups, and changing a forwarding port for one address also makes the same change for all other addresses in the same group.

The Reserved Multicast Table is accessed in the same manner as the Static Address Table, using the same indirect access registers. The Static Address and Reserved Multicast Table Control Register is used for indexing and read/write control, while the Reserved Multicast Address Table Entry 2 Register is used for the data fields.

5.3.3.1  Reserved Multicast Table Write Operation

1. Write the PORT_FORWARD value to the Reserved Multicast Address Table Entry 2 Register.
2. Write to the Static Address and Reserved Multicast Table Control Register.
   a) Write the TABLE_INDEX field with the 6-bit index value.
   b) Set the TABLE_SELECT bit to 1 to select the Reserved Multicast Table.
   c) Set the ACTION bit to 0 to indicate a write operation.
   d) Set the START_FINISH bit to 1 to initiate the operation.
3. When the operation is complete, the START_FINISH bit will be cleared automatically.

5.3.3.2  Reserved Multicast Table Read Operation

1. Write to the Static Address and Reserved Multicast Table Control Register.
   a) Write the TABLE_INDEX field with the 6-bit index value.
   b) Set the TABLE_SELECT bit to 1 to select the Reserved Multicast Table.
   c) Set the ACTION bit to 1 to indicate a read operation.
   d) Set the START_FINISH bit to 1 to initiate the operation.
2. When the operation is complete, the START_FINISH bit will be cleared automatically.
   a) Read the contents of the indexed entry from the Reserved Multicast Address Table Entry 2 Register.
5.3.3.3 Reserved Multicast Address Table Entry 2 Register

Address: 0x0424 - 0x0427 Size: 32 bits

<table>
<thead>
<tr>
<th>Bits</th>
<th>Description</th>
<th>Type</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>31:30</td>
<td>RESERVED</td>
<td>R/W</td>
<td>00b</td>
</tr>
<tr>
<td>29:7</td>
<td>RESERVED</td>
<td>RO</td>
<td>0x000000</td>
</tr>
<tr>
<td>6:0</td>
<td>PORT FORWARD</td>
<td>R/W</td>
<td>0x00</td>
</tr>
</tbody>
</table>

Each bit corresponds to a device port.
Bit 0 is for port 1
Bit 1 is for port 2, etc.
1 = Forward to the corresponding port
0 = Do not forward to the corresponding port

5.3.4 VLAN TABLE

An internal VLAN Table is used for VLAN lookup. If 802.1Q VLAN mode is enabled (Switch Lookup Engine Control 0 Register), this table will be used to retrieve the VLAN information that is associated with the ingress packet. The table holds 4096 entries - one for each possible VLAN. The table must be set up before 802.1Q VLAN is enabled. The VLAN table is accessed one entry at a time using the following indirect registers:

- VLAN Table Entry 0 Register
- VLAN Table Entry 1 Register
- VLAN Table Entry 2 Register
- VLAN Table Index Register
- VLAN Table Access Control Register

The table data fields are described in Figure 5-4 and Table 5-4.

FIGURE 5-4: VLAN TABLE STRUCTURE
TABLE 5-4: VLAN TABLE DATA FIELDS

<table>
<thead>
<tr>

<td>When 1, untag at that egress port. When 0, don’t untag.</td>
</tr>
<tr>
<td>PORT FORWARD</td>
<td>7 (1 per port)</td>
<td>VLAN port membership list. There is one bit per port, starting with the LSB which corresponds to port 1. A bit value of 1 indicates the associated port is included in the port membership list for that VID. When 0, that port is excluded.</td>
</tr>
</tbody>
</table>

5.3.4.1 VLAN Table Write Operation
1. Write to the VLAN Table Entry 0 Register, VLAN Table Entry 1 Register, and VLAN Table Entry 2 Register to set up the data fields as described in Figure 5-4 and Table 5-4.
2. Write the VLAN Index value in the VLAN Table Index Register. This is the 12-bit index (address) to select the table entry. It is equivalent to the VID which indexes the table during lookup.
3. Write the VLAN Table Access Control Register to specify a write operation, and set START (bit 7). When the operation is complete, bit 7 will be cleared automatically.

5.3.4.2 VLAN Table Read Operation
1. Write the VLAN Index value in the VLAN Table Index Register to select one of the 4k table entries.
2. Write the VLAN Table Access Control Register to specify a read operation and set START (bit 7). When the operation is complete, bit 7 will be cleared automatically.
3. Read the VLAN Table Entry 0 Register, VLAN Table Entry 1 Register, and VLAN Table Entry 2 Register to retrieve the read results from the VLAN table.

5.3.5 ACCESS CONTROL LIST (ACL) TABLE
ACL filtering is implemented individually per-port. The ACL tables are accessed using the Port N: Port Switch ACL Control Registers (0xN600 - 0xN6FF). The 16 entries in each ACL table are addressed indirectly by an index register.

Table 5-5 shows how the various fields of the ACL Table entries are mapped to data registers. The Port ACL Byte Enable MSB Register and Port ACL Byte Enable LSB Register make it possible to write or read any combination of bytes. This is useful for writing the Matching rule, Action rule and Process field separately. There are 16 bits in these byte enable registers, corresponding to the 16 data registers Port ACL Access 0 Register through Port ACL Access F Register. Note that the enable bits are applied in reverse order:

Bit 0 for the Port ACL Access F Register
Bit 1 for the Port ACL Access E Register
...-
Bit 15 for the Port ACL Access 0 Register

Also note that the Port ACL Access C Register is not used, so byte enable bit 3 is a don’t care.
5.3.5.1 ACL Table Read

1. Write to the Port ACL Access Control 0 Register with the table entry number (0 to 15) in the ACL Index field, and
   the Write/Read bit 4 cleared to zero. This one write to this register initiates the read operation.

2. Poll the Read Status bit in the Port ACL Access Control 0 Register to determine when the read operation is com-
   plete.

3. When the operation is complete, data may be retrieved from the Port ACL Access 0 Register through Port ACL
   Access F Register.

</tbody>
</table>
5.3.5.2 ACL Table Write

1. Write the ACL table entry values to the Port ACL Access 0 Register through Port ACL Access F Register.
2. Write the Port ACL Byte Enable MSB Register and Port ACL Byte Enable LSB Register to select which registers (Port ACL Access 0 Register through Port ACL Access F Register) are to be written into the ACL table.
3. Write to the Port ACL Access Control 0 Register with the table entry number in the ACL Index field, and the Write/Read bit 4 set to one. This one write to this register initiates the write operation.
4. The Write Status bit in the Port ACL Access Control 0 Register may be polled to determine when the operation is complete.

5.3.6 MANAGEMENT INFORMATION BASE (MIB) COUNTERS

There are 36 MIB counters per port. These counters accumulate a variety of statistics on ingress and egress traffic and events for network management. They are accessed indirectly using the Port MIB Control and Status Register and Port MIB Data Register. The Switch MIB Control Register provides global flush and freeze control of the MIB counters.

TABLE 5-6: MIB COUNTERS

</tbody>
</table>
### 5.3.6.1 MIB Counter Read Operation

Direct access registers are used to read the MIB counters. Separate access registers are provided for each port via the Port MIB Control and Status Register and Port MIB Data Register. All MIB Counters are read-clear. The steps for reading a counter are as follows:

1. Write the MIB Index to bits [23:16] of the Port MIB Control and Status Register.
2. Set the MIB Read Enable in bit 25 of the Port MIB Control and Status Register. This step and the previous step may be done together.
3. Read the MIB Read Enable / Count Valid in bit 25 of the Port MIB Control and Status Register. A '0' value indicates that the read is complete and the count is valid.
4. Read the count value from the Port MIB Data Register. For 36-bit counters, counter bits [35:32] are read from the Port MIB Control and Status Register. The Counter Overflow bit is also found in the Port MIB Control and Status Register.

</tr>
</tbody>
</table>
5.3.6.2 MIB Counter Freeze and Flush Functions

Counter freeze and flush functions are available on a port-by-port basis. Freezing or flushing counters is initiated by setting the appropriate bit in the Switch MIB Control Register. The freeze or flush function will be applied to all ports for which the flush and freeze functions have been enabled. To enable flush and freeze for a port, set bit 24 in the Port MIB Control and Status Register.

The following steps show an example of how flush and freeze are used to collect MIB statistics for all ports for a period of 1 second:

1. Set the MIB Flush and Freeze Enable bit 24 in the Port MIB Control and Status Register for all ports N.
2. Write 0x40 to the Switch MIB Control Register to freeze the MIB counters for all enabled ports.
3. Write 0xC0 to the Switch MIB Control Register to clear the MIB counters for all enabled ports (while continuing to also freeze the counters).
4. At the beginning of the 1 second period, write 0x00 to the Switch MIB Control Register to enable the counters.
5. At the end of the 1 second period, write 0x40 to the Switch MIB Control Register to freeze the counters.
6. Read each counter for each port.

5.4 MDIO Manageable Device (MMD) Registers (Indirect)

MMD registers provide indirect read/write access to up to 32 MMD device addresses with each device supporting up to 65,536 16-bit registers, as defined in Clause 22 of the IEEE 802.3 Specification. However, the KSZ9897S uses only a small fraction of the available registers. Refer to Table 5-7, "MMD Register Map" for a list of accessible MMD device addresses and their associated register addresses. Detailed descriptions of the supported MMD registers are provided in the following subsections. Additional information on the MII Management (MIIM) Interface is provided in Section 4.9.3, "MII Management (MIIM) Interface," on page 55.

The following two standard port registers serve as the portal registers to access the indirect MMD registers.

- PHY MMD Setup Register
- PHY MMD Data Register

<table>
<thead>
<tr>
<th>Device Address (hex)</th>
<th>Register Address (hex)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>2h</td>
<td>00h</td>
<td>MMD LED Mode Register</td>
</tr>
<tr>
<td>7h</td>
<td>3Ch</td>
<td>MMD EEE Advertisement Register</td>
</tr>
</tbody>
</table>

Example: MMD Register Write

Write MMD - Device Address 2h, Register 00h = 0010h to enable single-LED mode.

1. Write the PHY MMD Setup Register with 0002h // Set up register address for MMD – Device Address 2h.
2. Write the PHY MMD Data Register with 0000h // Select Register 00h of MMD – Device Address 2h.
3. Write the PHY MMD Setup Register with 4002h // Select register data for MMD – Device Address 2h, Reg. 00h.
4. Write the PHY MMD Data Register with 0010h // Write value 0010h to MMD – Device Address 2h, Reg. 00h.

Example: MMD Register Read

Read MMD - Device Address 7h, Register 3Ch for the LED mode status. Optional auto-increment is used.

1. Write the PHY MMD Setup Register with 0007h // Set up register address for MMD – Device Address 7h.
2. Write the PHY MMD Data Register with 003Ch // Select Register 3Ch of MMD – Device Address 7h.
3. Write the PHY MMD Setup Register with 8007h // Select register data for MMD – Device Address 7h, Reg. 3Ch.
4. Read the PHY MMD Data Register // Read data in MMD – Device Address 7h, Reg. 3Ch.
### 5.4.1 MMD LED MODE REGISTER

</tbody>
</table>
5.5 SGMII Registers (Indirect)

This section details the indirectly addressable SGMII registers, which are summarized in Table 5-8, "SGMII Register Map (Indirect)". The indirect SGMII register address space is 21 bits. Detailed descriptions of the supported SGMII registers are provided in the following subsections. Refer to Section 5.2.3, "Port N: Port SGMII Control Registers (0xN200 - 0xN2FF)," on page 128 for additional information on accessing the indirect SGMII registers.

The following two standard port registers serve as the portal registers to access the indirect SGMII registers:
- Port SGMII Address Register
- Port SGMII Data Register

### TABLE 5-8: SGMII REGISTER MAP (INDIRECT)

### 5.5.6 SGMII AUTO-NEGOTIATION LINK PARTNER BASE ABILITY REGISTER

Address: 0x1F0005

Size: 16 bits

When auto-negotiation is complete, this register holds auto-negotiation codeword received from the link partner. The field descriptions in this register are valid only when operating in SerDes mode (a.k.a. 1000BASE-X mode). When operating in SGMII mode, see SGMII Auto-Negotiation Status Register for auto-negotiation results.

5.5.10 SGMII AUTO-NEGOTIATION STATUS REGISTER

Address: 0x1F8002 Size: 16 bits

This register provides the results of the SGMII auto-negotiation. The SGMII Auto-Negotiation Control Register needs to be updated after the correct speed and duplex are detected in this register. For 1000BASE-X / SerDes link partners (non-SGMII), see SGMII Auto-Negotiation Link Partner Base Ability Register instead of this register for auto-negotiation results.

6.0 OPERATIONAL CHARACTERISTICS

6.1 Absolute Maximum Ratings*

Supply Voltage ($AVDDL$, $DVDDL$, $VDDLS$) ................................................................. -0.5 V to +1.8 V
Supply Voltage ($AVDDH$, $VDDIO$, $VDDHS$) ................................................................. -0.5 V to +5.0 V
Input Voltage (all inputs) ........................................................................................................ -0.5 V to +5.0 V
Output Voltage (all outputs) ..................................................................................................... -0.5 V to +5.0 V
Lead Temperature (soldering, 20 sec.) .................................................................................... +260°C
Storage Temperature ($TS$) ...................................................................................................... -65°C to +150°C
Maximum Junction Temperature ($TJ$) .................................................................................... +125°C
HBM ESD Performance ............................................................................................................ +/-6 kV

*Stresses exceeding those listed in this section could cause permanent damage to the device. This is a stress rating only. Exposure to absolute maximum rating conditions for extended periods may affect device reliability. Functional operation of the device at any condition exceeding those indicated in Section 6.2, "Operating Conditions***", Section 6.3, "Electrical Characteristics", or any other applicable section of this specification is not implied.

6.2 Operating Conditions**

Supply Voltage ($AVDDL$, $DVDDL$, $VDDLS$) ................................................................. +1.14 V to +1.26 V
Supply Voltage ($AVDDH$, $VDDHS$) ..................................................................................... +2.375 V to +2.625 V
Supply Voltage ($VDDIO$ @ 3.3V) .......................................................................................... +3.135 V to +3.465 V
Supply Voltage ($VDDIO$ @ 2.5V) .......................................................................................... +2.375 V to +2.625 V
Supply Voltage ($VDDIO$ @ 1.8V) .......................................................................................... +1.71 V to +1.89 V
Ambient Operating Temperature in Still Air ($T_A$) ............................................................... Note 6-1
Junction to Ambient Resistance ($\Theta_{JA}$) (Note 6-2) ............................................................ Note 6-3
Junction to Case Characterization ($\Psi_{JT}$) (Note 6-2) .......................................................... Note 6-4
Junction to Case Resistance ($\Theta_{JC}$) (Note 6-2) ................................................................. Note 6-4

Note 6-1 0°C to +70°C for commercial version, -40°C to +85°C for industrial version.
Note 6-2 $\Psi_{JT}$ and $\Theta_{JA}$ are under a 0 m/s air velocity. A 6-layer PCB is required for industrial applications.
Note 6-3 11.3°C/W on a 6-layer PCB per JESD51, 14.4°C/W on a 4-layer PCB per JESD51.
Note 6-4 1.5°C/W on a 6-layer PCB per JESD51, 1.21°C/W on a 4-layer PCB per JESD51.

**Proper operation of the device is ensured only within the ranges specified in this section.

6.4 Timing Specifications
This section details the various timing specifications of the device.

Note: The I²C interface timing adheres to the NXP I²C-Bus Specification (UM10204, Rev. 6) (high-speed mode and slower). Refer to the I²C-Bus Specification for additional information.

6.4.1 RGMII TIMING
Figure 6-1 illustrates the RGMII timing requirements.

</tbody>
</table>

Note 6-5 For cases where there is no (or insufficient) skew between the input data and input clock, it is possible to add internal delay to the TX_CLK pinout by setting the RGMII Ingress Internal Delay bit in the XMII Port Control 1 Register register. This feature reduces the setup time requirement and increases the hold time requirement nominally by 1.3ns.

Note 6-6 The RGMII interface adheres to the RGMII Specification Version 2.0, which specified that the driving device delay the output clock relative to the output data. This is the TSKEW parameter. This skew can be disabled by clearing the RGMII Egress Internal Delay bit in the XMII Port Control 1 Register register. Generally this is not recommended.

Note 6-7 For 10Mbps and 100Mbps, TCYC will scale to 400ns +/- 40ns and 40ns +/- 4 ns, respectively.

Note 6-8 0.75ns for VDDIO = 3.3V/2.5V, 1.0ns for VDDIO = 1.8V

</tr>
<tr>
<td>trw</td>
<td>Reset pulse width after power-up (warm-reset)</td>
<td>1</td>
<td></td>
<td></td>
<td>μs</td>
</tr>
</tbody>
</table>

**Note 1:** The recommended powering sequence is to bring up all voltages at the same time. If this cannot be done, \( \text{RESET}_N \) should be held low until all supplies are stable, then brought high. If using the SGMII block, a reset is recommended by setting bit 15 in the SGMII Control Register.

**Note 2:** After the de-assertion of reset, it is recommended to wait a minimum of 100 μs before starting to program the device through any interface.

**Note 3:** The recommended power down sequence is to power down the low voltage core before powering down the transceiver and digital I/O voltages, or to have all supplies power down in unison. Before the next power-up cycle, all supply voltages to the device should reach less than 0.4 V and there should be a minimum wait time of 150 ms from power-off to power-on.
6.5 Clock Specifications

A crystal or external clock source, such as an oscillator, is used to provide a 25MHz reference clock for the KSZ9897S. If an external clock source is used, the XO pin must be left floating. Since the XI/XO circuit is powered from AVDDH, the external clock source should also be powered from the same power rail. Figure 6-13 details the available connection methods. Table 6-12 details the recommended crystal specifications.

7.0 DESIGN GUIDELINES

This section provides general design guidelines for the following:

- Reset Circuit Guidelines
- Magnetics Connection and Selection Guidelines

7.1 Reset Circuit Guidelines

Figure 7-1 illustrates the recommended reset circuit for powering up the KSZ9897S if reset is triggered by the power supply.

**FIGURE 7-1: SIMPLE RESET CIRCUIT**

![Simple Reset Circuit Diagram]

Figure 7-2 illustrates a reset circuit recommended for applications where reset is driven by another device, such as a CPU. At power-on reset, R, C and D1 provide the necessary ramp rise time to reset the KSZ9897S. The RST_OUT_N from the CPU provides a warm reset after power-up.

**FIGURE 7-2: RESET CIRCUIT FOR CPU RESET INTERFACE**

![Reset Circuit for CPU Reset Interface Diagram]
7.2 Magnetics Connection and Selection Guidelines

A 1:1 isolation transformer is required at the line interface. For designs exceeding FCC requirements, utilize one with integrated common-mode chokes. An optional auto-transformer stage following the chokes provides additional common-mode noise and signal attenuation.

The KSZ9897S PHY port design incorporates voltage-mode transmit drivers and on-chip terminations. With the voltage-mode implementation, the transmit drivers supply the common-mode voltages to the four differential pairs. Therefore, the four transformer center tap pins on the KSZ9897S chip side should not be connected to any power supply source on the board; rather, the center tap pins should be separated from one another and connected through separate 0.1µF common-mode capacitors to ground. Separation is required because the common-mode voltage could be different between the differential pairs, depending on the connected speed mode.

Figure 7-3 details a typical magnetic interface circuit for the KSZ9897S PHY port.

**FIGURE 7-3:** TYPICAL MAGNETIC INTERFACE CIRCUIT

Table 7-1 provides a list of recommended magnetic characteristics.

8.0 PACKAGE INFORMATION

8.1 Package Marking Information

Legend:
- **t**: Temperature range designator (C = commercial, I = industrial)
- **R**: Product revision
- **nnn**: Internal code
- **e3**: Pb-free JEDEC® designator for Matte Tin (Sn)
- **YY**: Year code (last two digits of calendar year)
- **WW**: Week code (week of January 1 is week ‘01’)
- **NNN**: Alphanumeric traceability code

Note: In the event the full Microchip part number cannot be marked on one line, it will be carried over to the next line, thus limiting the number of available characters for customer-specific information.

* Standard device marking consists of Microchip part number, year code, week code and traceability code. For device marking beyond this, certain price adders apply. Please check with your Microchip Sales Office. For QTP devices, any special marking adders are included in QTP price.

THE MICROCHIP WEB SITE

Microchip provides online support via our WWW site at www.microchip.com. This web site is used as a means to make files and information easily available to customers. Accessible by using your favorite Internet browser, the web site contains the following information:

- **Product Support** – Data sheets and errata, application notes and sample programs, design resources, user’s guides and hardware support documents, latest software releases and archived software
- **General Technical Support** – Frequently Asked Questions (FAQ), technical support requests, online discussion groups, Microchip consultant program member listing
- **Business of Microchip** – Product selector and ordering guides, latest Microchip press releases, listing of seminars and events, listings of Microchip sales offices, distributors and factory representatives

CUSTOMER CHANGE NOTIFICATION SERVICE

Microchip’s customer notification service helps keep customers current on Microchip products. Subscribers will receive e-mail notification whenever there are changes, updates, revisions or errata related to a specified product family or development tool of interest.

To register, access the Microchip web site at www.microchip.com. Under “Support”, click on “Customer Change Notification” and follow the registration instructions.

CUSTOMER SUPPORT

Users of Microchip products can receive assistance through several channels:

- Distributor or Representative
- Local Sales Office
- Field Application Engineer (FAE)
- Technical Support

Customers should contact their distributor, representative or field application engineer (FAE) for support. Local sales offices are also available to help customers. A listing of sales offices and locations is included in the back of this document.

**Technical support is available through the web site at:** [http://www.microchip.com/support](http://www.microchip.com/support)
To order or obtain information, e.g., on pricing or delivery, refer to the factory or the listed sales office.

</table>

Device: KSZ9897S = 7-Port Switch with 1 SGMII, 1 RGMII/MII/RMII

Package: TX = 128-pin TQFP-EP

Temperature Range:
- C = 0°C to +70°C (Commercial)
- I = -40°C to +85°C (Industrial)

Tape and Reel Option:
- Blank = Standard packaging (tray)
- -TR = Tape and Reel (Note 1)

Examples:

a) KSZ9897STXC
   128-pin TQFP-EP package,
   Commercial temperature,
   Standard packaging

b) KSZ9897STXI-TR
   128-pin TQFP-EP package,
   Industrial temperature,
   Tape and reel

Note 1: Tape and Reel identifier only appears in the catalog part number description. This identifier is used for ordering purposes and is not printed on the device package. Check with your Microchip Sales Office for package availability with the Tape and Reel option.
Note the following details of the code protection feature on Microchip devices:

- Microchip products meet the specification contained in their particular Microchip Data Sheet.
- Microchip believes that its family of products is one of the most secure families of its kind on the market today, when used in the intended manner and under normal conditions.
- There are dishonest and possibly illegal methods used to breach the code protection feature. All of these methods, to our knowledge, require using the Microchip products in a manner outside the operating specifications contained in Microchip’s Data Sheets. Most likely, the person doing so is engaged in theft of intellectual property.
- Microchip is willing to work with the customer who is concerned about the integrity of their code.
- Neither Microchip nor any other semiconductor manufacturer can guarantee the security of their code. Code protection does not mean that we are guaranteeing the product as “unbreakable.”

Code protection is constantly evolving. We at Microchip are committed to continuously improving the code protection features of our products. Attempts to break Microchip’s code protection feature may be a violation of the Digital Millennium Copyright Act. If such acts allow unauthorized access to your software or other copyrighted work, you may have a right to sue for relief under that Act.

Information contained in this publication regarding device applications and the like is provided only for your convenience and may be superseded by updates. It is your responsibility to ensure that your application meets with your specifications. MICROCHIP MAKES NO REPRESENTATIONS OR WARRANTIES OF ANY KIND WHETHER EXPRESS OR IMPLIED, WRITTEN OR ORAL, STATUTORY OR OTHERWISE, RELATED TO THE INFORMATION, INCLUDING BUT NOT LIMITED TO ITS CONDITION, QUALITY, PERFORMANCE, MERCHANTABILITY OR FITNESS FOR PURPOSE. Microchip disclaims all liability arising from this information and its use. Use of Microchip devices in life support and/or safety applications is entirely at the buyer's risk, and the buyer agrees to defend, indemnify and hold harmless Microchip from any and all damages, claims, suits, or expenses resulting from such use. No licenses are conveyed, implicitly or otherwise, under any Microchip intellectual property rights unless otherwise stated.
