General Features

- Stand-Alone CAN 2.0B Controller with Integrated CAN Transceiver and Serial Peripheral Interface (SPI)
- Up to 1 Mb/s Operation
- Very Low Standby Current (10 µA, typical)
- Up to 10 MHz SPI Clock Speed
- Interfaces Directly with Microcontrollers with 2.7V to 5.5V I/Os
- Available in SSOP-28L and 6x6 QFN-28L
- Temperature Ranges:
  - Extended (E): -40°C to +125°C

CAN Controller Features

- \( V_{DD} \): 2.7 to 5.5V
- Implements CAN 2.0B (ISO11898-1)
- Three Transmit Buffers with Prioritization and Abort Features
- Two Receive Buffers
- Six Filters and Two Masks with Optional Filtering on the First Two Data Bytes
- Supports SPI Modes 0.0 and 1.1
- Specific SPI Commands to Reduce SPI Overhead
- Buffer Full and Request-to-Send Pins are Configurable as General Purpose I/Os
- One Interrupt Output Pin

CAN Transceiver Features

- \( V_{DDA} \): 4.5V to 5.5V
- CAN Bus Pins are Disconnected when Device is Unpowered:
  - An unpowered node or brown-out event will not load the CAN bus
- Detection of Ground Fault:
  - Permanent Dominant detection on \( T_{XD} \)
  - Permanent Dominant detection on bus
- Power-on Reset and Voltage Brown-Out Protection on \( V_{DDA} \) Pin
- Protection Against Damage Due to Short-Circuit Conditions (Positive or Negative Battery Voltage)
- Protection Against High-Voltage Transients in Automotive Environments
- Automatic Thermal Shutdown Protection
- Suitable for 12V and 24V Systems
- Meets or Exceeds Stringent Automotive Design Requirements, Including “Hardware Requirements for LIN, CAN and FlexRay Interfaces in Automotive Applications”, Version 1.3, May 2012
- High Noise Immunity Due to Differential Bus Implementation
- High-ESD Protection on CANH and CANL, Meets IEC61000-4-2 up to ±8 kV

Description

The MCP25625 is a complete, cost-effective and small footprint CAN solution that can be easily added to a microcontroller with an available SPI interface.

The MCP25625 interfaces directly with microcontrollers operating at 2.7V to 5.5V; there are no external level shifters required. In addition, the MCP25625 connects directly to the physical CAN bus, supporting all requirements for CAN high-speed transceivers.

The MCP25625 meets the automotive requirements for high-speed (up to 1 Mb/s), low quiescent current, Electromagnetic Compatibility (EMC) and Electrostatic Discharge (ESD).
MCP25625

Package Types

* Includes Exposed Thermal Pad (EP); see Table 1-1.
1.0 DEVICE OVERVIEW

A typical CAN solution consists of a CAN controller that implements the CAN protocol, and a CAN transceiver that serves as the interface to the physical CAN bus. The MCP25625 integrates both the CAN controller and the CAN transceiver. Therefore, it is a complete CAN solution that can be easily added to a microcontroller with an SPI interface.

1.1 Block Diagram

Figure 1-1 shows the block diagram of the MCP25625. The CAN transceiver is illustrated in the top half of the block diagram, see Section 6.0 “CAN Transceiver” for more details.

The CAN controller is depicted at the bottom half of the block diagram, and described in more detail in Section 3.0 “CAN Controller”.

Note 1: See Section 3.0 “CAN Controller” and Section 6.0 “CAN Transceiver” for further information.
1.3 Typical Application

Figure 1-2 shows an example of a typical application of the MCP25625. In this example, the microcontroller operates at 3.3V.

VDDA supplies the CAN transceiver and must be connected to 5V.

VDD, VIO of the MCP25625 are connected to the VDD of the microcontroller. The digital supply can range from 2.7V to 5.5V. Therefore, the I/O of the MCP25625 is connected directly to the microcontroller, no level shifters are required.

The TXD and RXD pins of the CAN transceiver must be externally connected to the TxCAN and RxCAN pins of the CAN controller.

The SPI interface is used to configure and control the CAN controller.

The INT pin of the MCP25625 signals an interrupt to the microcontroller. Interrupts need to be cleared by the microcontroller through SPI.

The usage of RxnBF and TxnRTS is optional, since the functions of these pins can be accessed through SPI. The RESET pin can optionally be pulled up to the VDD of the MCP25625 using a 10 kΩ resistor.

The CLKOUT pin provides the clock to the microcontroller.
2.0 MODES OF OPERATION

2.1 CAN Controller Modes of Operation

The CAN controller has five modes of operation:

• Configuration mode
• Normal mode
• Sleep mode
• Listen-Only mode
• Loopback mode

The operational mode is selected via the REQOP[2:0] bits in the CANCTRL register (see Register 4-34).

When changing modes, the mode will not actually change until all pending message transmissions are complete. The requested mode must be verified by reading the OPMOD[2:0] bits in the CANSTAT register (see Register 4-35).

2.2 CAN Transceiver Modes of Operation

The CAN transceiver has two modes of operation:

• Normal mode
• Standby mode

Normal mode is selected by applying a low level to the STBY pin. The driver block is operational and can drive the bus pins. The slopes of the output signals on CANH and CANL are optimized to produce minimal Electromagnetic Emissions (EME). The high-speed differential receiver is active.

Standby mode is selected by applying a high level to the STBY pin. In Standby mode, the transmitter and the high-speed part of the receiver are switched off to minimize power consumption. The low-power receiver and the wake-up filter are enabled in order to monitor the bus for activity. The receive pin (RXD) will show a delayed representation of the CAN bus, due to the wake-up filter.

2.3 Configuration Mode

The MCP25625 must be initialized before activation. This is only possible if the device is in Configuration mode. Configuration mode is automatically selected after power-up, a Reset or can be entered from any other mode by setting the REQOPx bits in the CANCTRL register. When Configuration mode is entered, all error counters are cleared. Configuration mode is the only mode where the following registers are modifiable:

• CNF1, CNF2, CNF3
• TXRTSCTRL
• Acceptance Filter registers

2.4 Normal Mode

Normal mode is the standard operating mode of the MCP25625. In this mode, the device actively monitors all bus messages and generates Acknowledge bits, error frames, etc. This is also the only mode in which the MCP25625 transmits messages over the CAN bus. Both the CAN controller and the CAN transceiver must be in Normal mode.

2.5 Sleep/Standby Mode

The CAN controller has an internal Sleep mode that is used to minimize the current consumption of the device. The SPI interface remains active for reading even when the MCP25625 is in Sleep mode, allowing access to all registers.

Sleep mode is selected via the REQOPx bits in the CANCTRL register. The OPMODx bits in the CANSTAT register indicate the operation mode. These bits should be read after sending the SLEEP command to the MCP25625. The MCP25625 is active and has not yet entered Sleep mode until these bits indicate that Sleep mode has been entered.

When in Sleep mode, the MCP25625 stops its internal oscillator. The MCP25625 will wake-up when bus activity occurs or when the microcontroller sets via the SPI interface. The WAKIF bit in the CANINTF register will “generate” a wake-up attempt (the WAKIE bit in the CANINTE register must also be set in order for the wake-up interrupt to occur).

The CAN transceiver must be in Standby mode in order to take advantage of the low standby current of the transceiver. After a wake-up, the microcontroller must put the transceiver back into Normal mode using the STBY pin.
2.5.1 WAKE-UP FUNCTIONS

The CAN transceiver will monitor the CAN bus for activity. The wake-up filter inside the transceiver is enabled to avoid a wake-up due to noise. In case there is activity on the CAN bus, the RXD pin will go low. The CAN bus wake-up function requires both CAN transceiver supply voltages to be in a valid range: $V_{DDA}$ and $V_{IO}$.

The CAN controller will detect a falling edge on the RxCAN pin and interrupt the microcontroller if the wake-up interrupt is enabled.

Since the internal oscillator is shut down while in Sleep mode, it will take some amount of time for the oscillator to start-up and the device to enable itself to receive messages. This Oscillator Start-up Timer (OST) is defined as 128 $T_{OSC}$.

The device will ignore the message that caused the wake-up from Sleep mode, as well as any messages that occur while the device is “waking up”. The device will wake-up in Listen-Only mode.

The microcontroller must set both the CAN controller and CAN transceiver to Normal mode before the MCP25625 will be able to communicate on the bus.

2.6 Listen-Only Mode

Listen-Only mode provides a means for the MCP25625 to receive all messages (including messages with errors) by configuring the RXM[1:0] bits in the RXBxCTRL register. This mode can be used for bus monitor applications or for detecting the baud rate in “hot plugging” situations.

For Auto-Baud Detection (ABD), it is necessary that at least two other nodes are communicating with each other. The baud rate can be detected empirically by testing different values until valid messages are received.

Listen-Only mode is a silent mode, meaning no messages will be transmitted while in this mode (including error flags or Acknowledge signals). In Listen-Only mode, both valid and invalid messages will be received regardless of filters and masks or RXM[1:0] bits in the RXBxCTRL registers. The error counters are reset and deactivated in this state. The Listen-Only mode is activated by setting the REQOPx bits in the CANCTRL register.

2.7 Loopback Mode

Loopback mode will allow internal transmission of messages from the transmit buffers to the receive buffers without actually transmitting messages on the CAN bus. This mode can be used in system development and testing.

In this mode, the ACK bit is ignored and the device will allow incoming messages from itself, just as if they were coming from another node. The Loopback mode is a silent mode, meaning no messages will be transmitted while in this state (including error flags or Acknowledge signals). The TxCAN pin will be in a Recessive state.

The filters and masks can be used to allow only particular messages to be loaded into the receive registers. The masks can be set to all zeros to provide a mode that accepts all messages. The Loopback mode is activated by setting the REQOPx bits in the CANCTRL register.
3.0 CAN CONTROLLER

The CAN controller implements the CAN protocol Version 2.0B. It is compatible with the ISO 11898-1 standard.

Figure 3-1 illustrates the block diagram of the CAN controller. The CAN controller consists of the following major blocks:

- CAN protocol engine
- TX handler
- RX handler
- SPI interface
- Control logic with registers and interrupt logic
- I/O pins
- Crystal oscillator

3.1 CAN Module

The CAN protocol engine, together with the TX and RX handlers, provide all the functions required to receive and transmit messages on the CAN bus. Messages are transmitted by first loading the appropriate message buffers and control registers. Transmission is initiated by using control register bits via the SPI interface or by using the transmit enable pins. Status and errors can be checked by reading the appropriate registers. Any message detected on the CAN bus is checked for errors and then matched against the user-defined filters to see if it should be moved into one of the two receive buffers.

3.2 Control Logic

The control logic block controls the setup and operation of the MCP25625 and contains the registers.

Interrupt pins are provided to allow greater system flexibility. There is one multipurpose interrupt pin (as well as specific interrupt pins) for each of the receive registers that can be used to indicate a valid message has been received and loaded into one of the receive buffers. Use of the specific interrupt pins is optional. The general purpose interrupt pin, as well as Status registers (accessed via the SPI interface), can also be used to determine when a valid message has been received.

Additionally, there are three pins available to initiate immediate transmission of a message that has been loaded into one of the three transmit registers. Use of these pins is optional, as initiating message transmissions can also be accomplished by utilizing control registers accessed via the SPI interface.

3.3 SPI Protocol Block

The microcontroller interfaces to the device via the SPI interface. Registers can be accessed using the SPI READ and WRITE commands. Specialized SPI commands reduce the SPI overhead.
3.4 CAN Buffers and Filters

Figure 3-2 shows the CAN buffers and filters in more detail. The MCP25625 has three transmit and two receive buffers, two acceptance masks (one per receive buffer) and a total of six acceptance filters.

FIGURE 3-2: CAN BUFFERS AND PROTOCOL ENGINE
3.5 CAN Protocol Engine

The CAN protocol engine combines several functional blocks, shown in Figure 3-3 and described below.

3.5.1 PROTOCOL FINITE STATE MACHINE

The heart of the engine is the Finite State Machine (FSM). The FSM is a sequencer that controls the sequential data stream between the TX/RX Shift register, the CRC register and the bus line. The FSM also controls the Error Management Logic (EML) and the parallel data stream between the TX/RX Shift registers and the buffers. The FSM ensures that the processes of reception, arbitration, transmission and error signaling are performed according to the CAN protocol. The automatic retransmission of messages on the bus line is also handled by the FSM.

3.5.2 CYCLIC REDUNDANCY CHECK

The Cyclic Redundancy Check register generates the Cyclic Redundancy Check (CRC) code, which is transmitted after either the control field (for messages with 0 data bytes) or the data field and is used to check the CRC field of incoming messages.

3.5.3 ERROR MANAGEMENT LOGIC

The Error Management Logic (EML) is responsible for the Fault confinement of the CAN device. Its two counters, the Receive Error Counter (REC) and the Transmit Error Counter (TEC), are incremented and decremented by commands from the bit stream processor. Based on the values of the error counters, the CAN controller is set into the states: error-active, error-passive or bus-off.

3.5.4 BIT TIMING LOGIC

The Bit Timing Logic (BTL) monitors the bus line input and handles the bus-related bit timing according to the CAN protocol. The BTL synchronizes on a Recessive-to-Dominant bus transition at Start-of-Frame (hard synchronization) and on any further Recessive-to-Dominant bus line transition if the CAN controller itself does not transmit a Dominant bit (resynchronization). The BTL also provides programmable time segments to compensate for the propagation delay time, phase shifts and to define the position of the sample point within the bit time. The programming of the BTL depends on the baud rate and external physical delay times.

FIGURE 3-3: CAN PROTOCOL ENGINE BLOCK DIAGRAM
3.6 Message Transmission

The transmit registers are described in Section 4.1 “Message Transmit Registers”.

3.6.1 TRANSMIT BUFFERS

The MCP25625 implements three transmit buffers. Each of these buffers occupies 14 bytes of SRAM and is mapped into the device memory map.

The first byte, TXBxCTRL, is a control register associated with the message buffer. The information in this register determines the conditions under which the message will be transmitted and indicates the status of the message transmission (see Register 4-1).

Five bytes are used to hold the Standard and Extended Identifiers, as well as other message arbitration information (see Registers 4-3 through 4-7). The last eight bytes are for the eight possible data bytes of the message to be transmitted (see Register 4-8).

At a minimum, the TXBxSIDH, TXBxSIDL and TXBxDLC registers must be loaded. If data bytes are present in the message, the TXBxDn registers must also be loaded. If the message is to use Extended Identifiers, the TXBxEIDn registers must also be loaded and the EXIDE bit in the TXBxSIDL register should be set.

Prior to sending the message, the microcontroller must initialize the TXxIE bit in the CANINTE register to enable or disable the generation of an interrupt when the message is sent.

Note: The TXREQ bit in the TXBxCTRL register must be clear (indicating the transmit buffer is not pending transmission) before writing to the transmit buffer.

3.6.2 TRANSMIT PRIORITY

Transmit priority is a prioritization within the CAN controller of the pending transmittable messages. This is independent from, and not necessarily related to, any prioritization implicit in the message arbitration scheme built into the CAN protocol.

Prior to sending the Start-of-Frame (SOF), the priority of all buffers that are queued for transmission are compared. The transmit buffer with the highest priority will be sent first. For example, if Transmit Buffer 0 has a higher priority setting than Transmit Buffer 1, Buffer 0 will be sent first.

If two buffers have the same priority setting, the buffer with the highest buffer number will be sent first. For example, if Transmit Buffer 1 has the same priority setting as Transmit Buffer 0, Buffer 1 will be sent first.

The TXP[1:0] bits in the TXBxCTRL register (see Register 4-1) allow the selection of four levels of transmit priority for each transmit buffer individually. A buffer with the TXPx bits equal to ‘11’ has the highest possible priority, while a buffer with the TXPx bits equal to ‘00’ has the lowest possible priority.

3.6.3 INITIATING TRANSMISSION

In order to initiate message transmission, the TXREQ bit in the TXBxCTRL register must be set for each buffer to be transmitted. This can be accomplished by:

• Writing to the register via the SPI WRITE command
• Sending the SPI RTS command
• Setting the TxnRTS pin low for the particular transmit buffer(s) that is to be transmitted

If transmission is initiated via the SPI interface, the TXREQ bit can be set at the same time as the TXPx priority bits.

When the TXREQ is set, the ABTF, MLOA and TXERR bits in the TXBxCTRL register will be cleared automatically.

Note: Setting the TXREQ bit in the TXBxCTRL register does not initiate a message transmission. It merely flags a message buffer as being ready for transmission. Transmission will start when the device detects that the bus is available.

Once the transmission has completed successfully, the TXREQ bit will be cleared, the TXxE bit in the CANINF register will be set and an interrupt will be generated if the TXxE bit in the CANINTE register is set.

If the message transmission fails, the TXREQ bit will remain set. This indicates that the message is still pending for transmission and one of the following condition flags will be set:

• If the message started to transmit but encountered an error condition, the TXERR bit in the TXBxCTRL register and the MERRF bit in the CANINF register will be set, and an interrupt will be generated on the INT pin if the MERR bit in the CANINTE register is set.
• If arbitration is lost, the MLOA bit in the TXBxCTRL register will be set.

Note: If One-Shot mode is enabled (OSM bit in the CANCTRL register), the above conditions will still exist. However, the TXREQ bit will be cleared and the message will not attempt transmission a second time.
3.6.4 ONE-SHOT MODE

One-Shot mode ensures that a message will only attempt to transmit one time. Normally, if a CAN message loses arbitration or is destroyed by an error frame, the message is retransmitted. With One-Shot mode enabled, a message will only attempt to transmit one time, regardless of arbitration loss or error frame.

One-Shot mode is required to maintain time slots in deterministic systems, such as TTCAN.

3.6.5 TxnRTS PINS

The TxnRTS pins are input pins that can be configured as:

- Request-to-Send inputs, which provide an alternative means of initiating the transmission of a message from any of the transmit buffers
- Standard digital inputs

Configuration and control of these pins is accomplished using the TXRTSCTRL register (see Register 4-2). The TXRTSCTRL register can only be modified when the CAN controller is in Configuration mode (see Section 2.0 “Modes of Operation”). If configured to operate as a Request-to-Send pin, the pin is mapped into the respective TXREQ bit in the TXBxCTRL register for the transmit buffer. The TXREQ bit is latched by the falling edge of the TxnRTS pin. The TxnRTS pins are designed to allow them to be tied directly to the RxnBF pins to automatically initiate a message transmission when the RxnBF pin goes low.

The TxnRTS pins have internal pull-up resistors of 100 kΩ (nominal).

3.6.6 ABORTING TRANSMISSION

The MCU can request to abort a message in a specific message buffer by clearing the associated TXREQ bit.

In addition, all pending messages can be requested to be aborted by setting the ABAT bit in the CANCTRL register. This bit MUST be reset (typically, after the TXREQ bits have been verified to be cleared) to continue transmitting messages. The ABTF flag in the TXBxCTRL register will only be set if the abort was requested via the ABAT bit in the CANCTRL register. Aborting a message by resetting the TXREQ bit does NOT cause the ABTF bit to be set.

Note 1: Messages that were transmitting when the abort was requested will continue to transmit. If the message does not successfully complete transmission (i.e., lost arbitration or was interrupted by an error frame), it will then be aborted.

2: When One-Shot mode is enabled, if the message is interrupted due to an error frame or loss of arbitration, the ABTF bit in the TXBxCTRL register will be set.

3.7 Message Reception

The registers required for message reception are described in Section 4.2 “Message Receive Registers”.

3.7.1 RECEIVE MESSAGE BUFFERING

The MCP25625 includes two full receive buffers with multiple acceptance filters for each. There is also a separate Message Assembly Buffer (MAB) that acts as a third receive buffer (see Figure 3-6).

3.7.1.1 Message Assembly Buffer

Of the three receive buffers, the MAB is always committed to receiving the next message from the bus. The MAB assembles all messages received. These messages will be transferred to the RXBx buffers (see Registers 4-12 to 4-17) only if the acceptance filter criteria is met.

3.7.1.2 RXB0 and RXB1

The remaining two receive buffers, called RXB0 and RXB1, can receive a complete message from the protocol engine via the MAB. The MCU can access one buffer, while the other buffer is available for message reception, or for holding a previously received message.

Note: The entire content of the MAB is moved into the receive buffer once a message is accepted. This means that regardless of the type of identifier (Standard or Extended) and the number of data bytes received, the entire receive buffer is overwritten with the MAB contents. Therefore, the contents of all registers in the buffer must be assumed to have been modified when any message is received.

3.7.1.3 Receive Flags/interrupts

When a message is moved into either of the receive buffers, the appropriate RXxF bit in the CANINTF register is set. This bit must be cleared by the MCU in order to allow a new message to be received into the buffer. This bit provides a positive lockout to ensure that the MCU has finished with the message before the CAN controller attempts to load a new message into the receive buffer.

If the RXxE bit in the CANINTE register is set, an interrupt will be generated on the INT pin to indicate that a valid message has been received. In addition, the associated RXnBF pin will drive low if configured as a receive buffer full pin. See Section 3.7.4 “Rx0BF and Rx1BF Pins” for details.

3.7.2 RECEIVE PRIORITY

RXB0, the higher priority buffer, has one mask and two message acceptance filters associated with it. The received message is applied to the mask and filters for RXB0 first.

RXB1 is the lower priority buffer, with one mask and four acceptance filters associated with it.

In addition to the message being applied to the RB0 mask and filters first, the lower number of acceptance filters makes the match on RXB0 more restrictive and implies a higher priority for that buffer.

When a message is received, the RXBxCTRL[3:0] bits will indicate the acceptance filter number that enabled reception and whether the received message is a remote transfer request.

3.7.2.1 Rollover

Additionally, the RXBOCTRL register can be configured such that, if RXB0 contains a valid message and another valid message is received, an overflow error will not occur and the new message will be moved into RXB1, regardless of the acceptance criteria of RXB1.

3.7.2.2 RXM[1:0] Bits

The RXM[1:0] bits in the RXBxCTRL register set special Receive modes. Normally, these bits are cleared to ‘00’ to enable reception of all valid messages as determined by the appropriate acceptance filters. In this case, the determination of whether or not to receive standard or extended messages is determined by the EXIDE bit in the RFxSIDL register.

If the RXMx bits are set to ‘11’, the buffer will receive all messages, regardless of the values of the acceptance filters. Also, if a message has an error before the End-of-Frame (EOF), that portion of the message assembled in the MAB before the error frame will be loaded into the buffer. This mode has some value in debugging a CAN system and would not be used in an actual system environment.

Setting the RXMx bits to ‘01’ or ‘10’ is not recommended.
3.7.3 START-OF-FRAME SIGNAL

If enabled, the Start-of-Frame signal is generated on the SOF bit at the beginning of each CAN message detected on the RxCAN pin.

The RxCAN pin monitors an Idle bus for a Recessive-to-Dominant edge. If the Dominant condition remains until the sample point, the MCP25625 interprets this as a SOF and a SOF pulse is generated. If the Dominant condition does not remain until the sample point, the MCP25625 interprets this as a glitch on the bus and no SOF signal is generated. Figure 3-5 illustrates SOF signaling and glitch filtering.

As with One-Shot mode, one use for SOF signaling is for TTCAN-type systems. In addition, by monitoring both the RxCAN pin and the SOF bit, an MCU can detect early physical bus problems by detecting small glitches before they affect the CAN communication.

3.7.4 Rx0BF AND Rx1BF PINS

In addition to the INT pin, which provides an interrupt signal to the MCU for many different conditions, the Receive Buffer Full pins (Rx0BF and Rx1BF) can be used to indicate that a valid message has been loaded into RXB0 or RXB1, respectively. The pins have three different configurations (see Table 3-1):

1. Disabled
2. Buffer Full Interrupt
3. Digital Output

3.7.4.3 Configured as Digital Output

When used as digital outputs, the BxBFM bits in the BFPCTRL register must be cleared and the BxBFE bits must be set for the associated buffer. In this mode, the state of the pin is controlled by the BxBFS bits in the same register. Writing a '1' to the BxBFS bits will cause a high level to be driven on the associated buffer full pin, while a '0' will cause the pin to drive low. When using the pins in this mode, the state of the pin should be modified only by using the SPI BIT MODIFY command to prevent glitches from occurring on either of the buffer full pins.

**Note:** Messages received in the MAB are initially applied to the mask and filters of RXB0. In addition, only one filter match occurs (e.g., if the message matches both RXF0 and RXF2, the match will be for RXF0 and the message will be moved into RXB0).
FIGURE 3-7: RECEIVE FLOW FLOWCHART

    - Yes: RXB1
    - No: RXB1
16. Determines if the Receive register is empty and able to accept a new message.
17. Determines if RXB0 can roll over into RXB1 if it is full.
3.7.5 MESSAGE ACCEPTANCE FILTERS AND MASKS

The message acceptance filters and masks are used to determine if a message in the Message Assembly Buffer should be loaded into either of the receive buffers (see Figure 3-9). Once a valid message has been received into the MAB, the identifier fields of the message are compared to the filter values. If there is a match, that message will be loaded into the appropriate receive buffer.

The registers required for message filtering are described in Section 4.3 “Acceptance Filter Registers”.

3.7.5.1 Data Byte Filtering

When receiving standard data frames (11-bit identifier), the MCP25625 automatically applies 16 bits of masks and filters, normally associated with Extended Identifiers, to the first 16 bits of the data field (data bytes 0 and 1). Figure 3-8 illustrates how masks and filters apply to extended and standard data frames.

Data byte filtering reduces the load on the MCU when implementing Higher Layer Protocols (HLPs) that filter on the first data byte (e.g., DeviceNet™).

3.7.5.2 Filter Matching

The filter masks (see Registers 4-22 through 4-25) are used to determine which bits in the identifier are examined with the filters. A truth table is shown in Table 3-2 that indicates how each bit in the identifier is compared to the masks and filters to determine if the message should be loaded into a receive buffer. The mask essentially determines which bits to apply the acceptance filters to. If any mask bit is set to a zero, that bit will automatically be accepted, regardless of the filter bit.

16-Bit Data Filtering*

* The two MSbs' (EID17 and EID16) mask and filter bits are not used.
3.7.5.3 FILHIT Bits

Filter matches on received messages can be determined by the FILHIT[2:0] bits in the associated RXBxCTRL register. The FILHIT0 bit in the RXB0CTRL register is associated with Buffer 0 and the FILHIT[2:0] bits in the RXB1CTRL register are associated with Buffer 1.

The three FILHITx bits for Receive Buffer 1 (RXB1) are coded as follows:

- 101 = Acceptance Filter 5 (RXF5)
- 100 = Acceptance Filter 4 (RXF4)
- 011 = Acceptance Filter 3 (RXF3)
- 010 = Acceptance Filter 2 (RXF2)
- 001 = Acceptance Filter 1 (RXF1)
- 000 = Acceptance Filter 0 (RXF0)

Note: ‘000’ and ‘001’ can only occur if the BUKT bit in RXB0CTRL is set, allowing RXB0 messages to roll over into RXB1.

RXB0CTRL contains two copies of the BUKT bit (BUKT1) and the FILHIT[0] bit.

The coding of the BUKT bit enables these three bits to be used similarly to the FILHITx bits in the RXB1CTRL register and to distinguish a hit on filters, RXF0 and RXF1, in either RXB0 or after a rollover into RXB1.

- 111 = Acceptance Filter 1 (RXB1)
- 110 = Acceptance Filter 0 (RXB0)
- 001 = Acceptance Filter 1 (RXB1)
- 000 = Acceptance Filter 0 (RXB0)

If the BUKT bit is clear, there are six codes corresponding to the six filters. If the BUKT bit is set, there are six codes corresponding to the six filters, plus two additional codes corresponding to the RXF0 and RXF1 filters that roll over into RXB1.

3.7.5.4 Multiple Filter Matches

If more than one acceptance filter matches, the FILHITx bits will encode the binary value of the lowest numbered filter that matched. For example, if filters, RXF2 and RXF4, match, FILHITx will be loaded with the value for RXF2. This essentially prioritizes the acceptance filters with a lower numbered filter having higher priority. Messages are compared to filters in ascending order of filter number. This also ensures that the message will only be received into one buffer. This implies that RXB0 has a higher priority than RXB1.

3.7.5.5 Configuring the Masks and Filters

The Mask and Filter registers can only be modified when the MCP25625 is in Configuration mode (see Section 2.0 “Modes of Operation”).

Note: The Mask and Filter registers read all ‘0’s when in any mode except Configuration mode.
3.8 CAN Bit Time

The Nominal Bit Rate (NBR) is the number of bits per second transmitted on the CAN bus (see Equation 3-1).

\[
NBR = \frac{1}{NBT}
\]

The Nominal Bit Time (NBT) is made up of four non-overlapping segments. Each of these segments is made up of an integer number of so called Time Quanta (T_Q).

The length of each Time Quantum is based on the oscillator period (TOSC). Equation 3-2 illustrates how the Time Quantum can be programmed using the Baud Rate Prescaler (BRP):

\[
T_Q = 2 \times (BRP_{5:0} + 1) \times TOSC = 2 \times \frac{(BRP_{5:0} + 1)}{FOSC}
\]

Figure 3-10 illustrates how the Nominal Bit Time is made up of four segments:

- **Synchronization Segment (SYNC)** – Synchronizes the different nodes connected on the CAN bus. A bit edge is expected to be within this segment. Based on the CAN protocol, the Synchronization Segment is 1 T_Q. See Section 3.8.3 “Synchronization” for more details on synchronization.
- **Propagation Segment (PRSEG)** – Compensates for the propagation delay on the bus. It is programmable from 1 to 8 T_Q.
- **Phase Segment 1 (PHSEG1)** – This time segment compensates for errors that may occur due to phase shifts in the edges. The time segment may be automatically lengthened during resynchronization to compensate for the phase shift. It is programmable from 1 to 8 T_Q.
- **Phase Segment 2 (PHSEG2)** – This time segment compensates for errors that may occur due to phase shifts in the edges. The time segment may be automatically shortened during resynchronization to compensate for the phase shift. It is programmable from 2 to 8 T_Q.

The total number of Time Quanta in a Nominal Bit Time is programmable and can be calculated using Equation 3-3.

\[
\frac{NBT}{T_Q} = Sync + PRSEG + PHSEG1 + PHSEG2
\]
3.8.1 SAMPLE POINT
The sample point is the point in the Nominal Bit Time at which the logic level is read and interpreted. The CAN bus can be sampled once or three times, as configured by the SAM bit in the CNF2 register:

- SAM = 0: The sample point is located between PHSEG1 and PHSEG2.
- SAM = 1: One sample point is located between PHSEG1 and PHSEG2. Additionally, two samples are taken at one-half TQ intervals prior to the end of PHSEG1, with the value of the bit being determined by a majority decision.

The sample point in percent can be calculated using Equation 3-4.

**EQUATION 3-4: SAMPLE POINT**

\[
SP = \left(\frac{PRSEG + PHSEG1}{NBT}\right) \times 100
\]

3.8.2 INFORMATION PROCESSING TIME
The Information Processing Time (IPT) is the time required for the CAN controller to determine the bit level of a sampled bit. The IPT for the MCP25625 is 2 TQ. Therefore, the minimum of PHSEG2 is also 2 TQ.

3.8.3 SYNCHRONIZATION
To compensate for phase shifts between the oscillator frequencies of the nodes on the bus, each CAN controller must be able to synchronize to the relevant edge of the incoming signal.

The CAN controller expects an edge in the received signal to occur within the SYNC segment. Only Recessive-to-Dominant edges are used for synchronization.

There are two mechanisms used for synchronization:

- **Hard Synchronization** – Forces the edge that has occurred to lie within the SYNC segment. The bit time counter is restarted with SYNC.
- **Resynchronization** – If the edge falls outside the SYNC segment, PHSEG1 and PHSEG2 will be adjusted.

For a more detailed description of the CAN synchronization, please refer to AN754, “Understanding Microchip’s CAN Module Bit Timing” (DS00754) and ISO11898-1.

3.8.4 SYNCHRONIZATION JUMP WIDTH
The Synchronization Jump Width (SJW) is the maximum amount PHSEG1 and PHSEG2 can be adjusted during resynchronization. SJW is programmable from 1 to 4 TQ.

3.8.5 OSCILLATOR TOLERANCE
According to the CAN specification, the bit timing requirements allow ceramic resonators to be used in applications with transmission rates of up to 125 kbps, as a rule of thumb. For the full bus speed range of the CAN protocol, a quartz oscillator is required. A maximum node-to-node oscillator variation of 1.58% is allowed.

The oscillator tolerance \( df \), around the nominal frequency of the oscillator \( f_{nom} \), is defined in Equation 3-5.

Equation 3-6 and Equation 3-7 describe the conditions for the maximum tolerance of the oscillator.

**EQUATION 3-5: OSCILLATOR TOLERANCE**

\[
(1 - df) \times (f_{nom} \leq F_{OSC} \leq (1 + df) \times f_{nom})
\]

**EQUATION 3-6: CONDITION 1**

\[
df \leq \frac{SJW}{2 \times 10 \times \frac{NBT}{TQ}}
\]

**EQUATION 3-7: CONDITION 2**

\[
df \leq \frac{\min(PHSEG1, PHSEG2)}{2 \times \left(13 \times \frac{NBT}{TQ} - PHSEG2\right)}
\]
3.8.6 PROPAGATION DELAY

Figure 3-11 illustrates the propagation delay between two CAN nodes on the bus. Assuming Node A is transmitting a CAN message, the transmitted bit will propagate from the transmitting CAN Node A, through the transmitting CAN transceiver, over the CAN bus, through the receiving CAN transceiver into the receiving CAN Node B.

During the arbitration phase of a CAN message, the transmitter samples the bus and checks if the transmitted bit matches the received bit. The transmitting node has to place the sample point after the maximum propagation delay.

Equation 3-8 describes the maximum propagation delay, where $t_{TXD - RXD}$ is the propagation delay of the transceiver, 235 ns for the MCP25625; $T_{BUS}$ is the delay on the CAN bus, approximately 5 ns/m. The factor two comes from the worst case, when Node B starts transmitting exactly when the bit from Node A arrives.

$$T_{PROP} = 2 \times (t_{TXD - RXD} + T_{BUS})$$

FIGURE 3-11: PROPAGATION DELAY
3.8.7 BIT TIME CONFIGURATION

EXAMPLE

The following example illustrates the configuration of the CAN Bit Time registers. Assuming we want to set up a CAN network in an automobile with the following parameters:

- 500 kbps Nominal Bit Rate (NBR)
- Sample point between 60 and 80% of the Nominal Bit Time (NBT)
- 40 meters minimum bus length

Table 3-3 illustrates how the bit time parameters are calculated. Since the parameters depend on multiple constraints and equations, and are calculated using an iterative process, it is recommended to enter the equations into a spreadsheet.

A detailed description of the Bit Time Configuration registers can be found in Section 4.4 “Bit Time Configuration Registers”.

3.9 Error Detection

The CAN protocol provides sophisticated error detection mechanisms. The following errors can be detected.

The registers required for error detection are described in Section 4.5 “Error Detection Registers”.

3.9.1 CRC ERROR

With the Cyclic Redundancy Check (CRC), the transmitter calculates special check bits for the bit sequence from the Start-of-Frame until the end of the data field. This CRC sequence is transmitted in the CRC field. The receiving node also calculates the CRC sequence using the same formula and performs a comparison to the received sequence. If a mismatch is detected, a CRC error has occurred and an error frame is generated; the message is repeated.

3.9.2 ACKNOWLEDGE ERROR

In the Acknowledge field of a message, the transmitter checks if the Acknowledge slot (which has been sent out as a Recessive bit) contains a Dominant bit. If not, no other node has received the frame correctly. An Acknowledge error has occurred, an error frame is generated and the message will have to be repeated.

3.9.3 FORM ERROR

If a node detects a Dominant bit in one of the four segments (including End-of-Frame, inter-frame space, Acknowledge delimiter or CRC delimiter), a form error has occurred and an error frame is generated. The message is repeated.

3.9.4 BIT ERROR

A bit error occurs if a transmitter detects the opposite bit level to what it transmitted (i.e., transmitted a Dominant and detected a Recessive, or transmitted a Recessive and detected a Dominant).

Exception: In the case where the transmitter sends a Recessive bit, and a Dominant bit is detected during the arbitration field and the Acknowledge slot, no bit error is generated because normal arbitration is occurring.

3.9.5 STUFF ERROR

If, between the Start-of-Frame and the CRC delimiter, six consecutive bits with the same polarity are detected, the bit-stuffing rule has been violated. A stuff error occurs and an error frame is generated; the message is repeated.

3.9.6 ERROR STATES

Detected errors are made known to all other nodes via error frames. The transmission of the erroneous message is aborted and the frame is repeated as soon as possible. Furthermore, each CAN node is in one of the three error states according to the value of the internal error counters:

- Error-active
- Error-passive
- Bus-off (transmitter only)

The error-active state is the usual state where the node can transmit messages and active error frames (made of Dominant bits) without any restrictions.

In the error-passive state, messages and passive error frames (made of Recessive bits) may be transmitted.

The bus-off state makes it temporarily impossible for the station to participate in the bus communication. During this state, messages can neither be received nor transmitted. Only transmitters can go bus-off.

3.10 Error Modes and Error Counters

The MCP25625 contains two error counters: the Receive Error Counter (REC) (see Register 4-30) and the Transmit Error Counter (TEC) (see Register 4-29). The values of both counters can be read by the MCU. These counters are incremented/decremented in accordance with the CAN bus specification.

The MCP25625 is error-active if both error counters are below the error-passive limit of 128.

The device is error-passive if at least one of the error counters equals or exceeds 128.

The device goes to bus-off if the TEC exceeds the bus-off limit of 255. The device remains in this state until the bus-off recovery sequence is received. The bus-off recovery sequence consists of 128 occurrences of 11 consecutive Recessive bits (see Figure 3-12).

Note: The MCP25625, after going bus-off, will recover back to error-active without any intervention by the MCU if the bus remains Idle for 128 x 11 bit times. If this is not desired, the error Interrupt Service Routine (ISR) should address this.

The current Error mode of the MCP25625 can be read by the MCU via the EFLG register (see Register 4-31).

Additionally, there is an error state warning flag bit (EWARN bit in the EFLG register), which is set if at least one of the error counters equals or exceeds the error warning limit of 96. EWARN is reset if both error counters are less than the error warning limit.
3.11 Interrupts

The MCP25625 has eight sources of interrupts. The CANINTE register contains the individual interrupt enable bits for each interrupt source. The CANINTF register contains the corresponding interrupt flag bit for each interrupt source. When an interrupt occurs, the INT pin is driven low by the MCP25625 and will remain low until the interrupt is cleared by the MCU. An interrupt can not be cleared if the respective condition still prevails.

It is recommended that the BIT MODIFY command be used to reset the flag bits in the CANINTF register, rather than normal write operations. This is done to prevent unintentionally changing a flag that changes during the WRITE command, potentially causing an interrupt to be missed.

It should be noted that the CANINTF flags are read/write and an interrupt can be generated by the microcontroller setting any of these bits, provided the associated CANINTE bit is also set.

The Interrupt registers are described in Section 4.6 “Interrupt Registers”.

3.11.1 INTERRUPT CODE BITS

The source of a pending interrupt is indicated in the ICOD[2:0] (Interrupt Code) bits in the CANSTAT register, as indicated in Register 4-35. In the event that multiple interrupts occur, the INT pin will remain low until all interrupts have been reset by the MCU. The ICOD bits will reflect the code for the highest priority interrupt that is currently pending. Interrupts are internally prioritized, such that the lower the ICODx value, the higher the interrupt priority. Once the highest priority interrupt condition has been cleared, the code for the next highest priority interrupt that is pending (if any) will be reflected by the ICODx bits (see Table 3-4). Only those interrupt sources that have their associated CANINTE enable bit set will be reflected in the ICODx bits.

### TABLE 3-4: ICOD[2:0] DECODE

</tr>
<tr>
<td>111</td>
<td>ERR+WAK+TX0+TX1+TX2+RX0+RX1</td>
</tr>
</tbody>
</table>

**Note:** ERR is associated with the ERRIE bit in the CANINTE register.
3.11.2 TRANSMIT INTERRUPT
When the transmit interrupt is enabled \((TXxIE = 1)\) in the CANINTE register, an interrupt will be generated on the INT pin once the associated transmit buffer becomes empty and is ready to be loaded with a new message. The TXxIF bit in the CANINTF register will be set to indicate the source of the interrupt. The interrupt is cleared by clearing the TXxIF bit.

3.11.3 RECEIVE INTERRUPT
When the receive interrupt is enabled \((RXxIE = 1)\) in the CANINTE register, an interrupt will be generated on the INT pin once a message has been successfully received and loaded into the associated receive buffer. This interrupt is activated immediately after receiving the EOF field. The RXxIF bit in the CANINTF register will be set to indicate the source of the interrupt. The interrupt is cleared by clearing the RXxIF bit.

3.12 Message Error Interrupt
When an error occurs during the transmission or reception of a message, the message error flag \((MERRF)\) in the CANINTF register) will be set, and if the MERRE bit in the CANINTE register is set, an interrupt will be generated on the INT pin. This is intended to be used to facilitate baud rate determination when used in conjunction with Listen-Only mode.

3.12.1 BUS ACTIVITY WAKE-UP INTERRUPT
When the CAN controller is in Sleep mode and the bus activity wake-up interrupt is enabled \((WAKIE = 1)\) in the CANINTE register), an interrupt will be generated on the INT pin when activity is detected on the CAN bus. This interrupt causes the CAN controller to exit Sleep mode. The interrupt is reset by clearing the WAKIF bit.

Note: The CAN controller wakes up into Listen-Only mode.

3.12.2 ERROR INTERRUPT
When the error interrupt is enabled \((ERRIE = 1)\) in the CANINTE register), an interrupt is generated on the INT pin if an overflow condition occurs, or if the error state of the transmitter or receiver has changed. The Error Flag (EFLG) register will indicate one of the following conditions.

3.12.2.1 Receiver Overflow
An overflow condition occurs when the MAB has assembled a valid receive message (the message meets the criteria of the acceptance filters) and the receive buffer associated with the filter is not available for loading a new message. The associated RXxOVR bit in the EFLG register will be set to indicate the overflow condition. This bit must be cleared by the microcontroller.

3.12.2.2 Receiver Warning
The REC has reached the MCU warning limit of 96.

3.12.2.3 Transmitter Warning
The TEC has reached the MCU warning limit of 96.

3.12.2.4 Receiver Error-Passive
The REC has exceeded the error-passive limit of 127 and the device has gone to error-passive state.

3.12.2.5 Transmitter Error-Passive
The TEC has exceeded the error-passive limit of 127 and the device has gone to error-passive state.

3.12.2.6 Bus-Off
The TEC has exceeded 255 and the device has gone to bus-off state.

3.12.3 INTERRUPT ACKNOWLEDGE
Interrupts are directly associated with one or more status flags in the CANINTF register. Interrupts are pending as long as one of the flags is set. Once an interrupt flag is set by the device, the flag can not be reset by the MCU until the interrupt condition is removed.

3.13 Oscillator
The MCP25625 is designed to be operated with a crystal or ceramic resonator connected to the OSC1 and OSC2 pins. The MCP25625 oscillator design requires the use of a parallel cut crystal. Use of a series cut crystal may give a frequency out of the crystal manufacturer’s specifications. A typical oscillator circuit is shown in Figure 3-13. The MCP25625 may also be driven by an external clock source connected to the OSC1 pin, as shown in Figure 3-14 and Figure 3-15.

3.13.1 OSCILLATOR START-UP TIMER
The MCP25625 utilizes an Oscillator Start-up Timer (OST) that holds the MCP25625 in Reset to ensure that the oscillator has stabilized before the internal state machine begins to operate. The OST keeps the device in a Reset state for 128 OSC1 clock cycles after the occurrence of a Power-on Reset, SPI Reset, after the assertion of the RESET pin, and after a wake-up from Sleep mode. Note that no SPI protocol operations are to be attempted until after the OST has expired.

Note: The CAN controller wakes up into Listen-Only mode.
3.13.2 CLKOUT PIN

The CLKOUT pin is provided to the system designer for use as the main system clock or as a clock input for other devices in the system. The CLKOUT has an internal prescaler, which can divide $F_{\text{OSC}}$ by 1, 2, 4 and 8. The CLKOUT function is enabled and the prescaler is selected via the CANCTRL register (see Register 4-34).

**Note:** The maximum frequency on CLKOUT is specified as 25 MHz (see Table 7-5).

The CLKOUT pin will be active upon system Reset and default to the slowest speed (divide-by-8) so that it can be used as the MCU clock.

When Sleep mode is requested, the CAN controller will drive sixteen additional clock cycles on the CLKOUT pin before entering Sleep mode. The Idle state of the CLKOUT pin in Sleep mode is low. When the CLKOUT function is disabled (CLKEN = 0 in the CANCTRL register), the CLKOUT pin is in a high-impedance state.

The CLKOUT function is designed to ensure that $t_{\text{HCLKOUT}}$ and $t_{\text{LCLKOUT}}$ timings are preserved when the CLKOUT pin function is enabled, disabled or the prescaler value is changed.

**FIGURE 3-13: CRYSTAL/CERAMIC RESONATOR OPERATION**

**Note 1:** A Series Resistor ($R_S$) may be required for AT strip-cut crystals.

**Note 2:** The Feedback Resistor ($R_F$) is typically in the range of 2 to 10 MΩ.

**FIGURE 3-14: EXTERNAL CLOCK SOURCE**

**Note 1:** A resistor to ground may be used to reduce system noise. This may increase system current.

**Note 2:** Duty cycle restrictions must be observed (see Table 7-2).
Figure 3-15: External Series Resonant Crystal Oscillator Circuit

`330 kΩ`

**Note 1:** Duty cycle restrictions must be observed (see Table 7-2).

### Table 3-5: Capacitor Selection for Ceramic Resonators

<table>
<thead>
<tr>
<th>Typical Capacitor Values Used:</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Mode</strong></td>
<td><strong>Freq.</strong></td>
</tr>
<tr>
<td>HS</td>
<td>8.0 MHz</td>
</tr>
<tr>
<td>16.0 MHz</td>
<td></td>
</tr>
</tbody>
</table>

Capacitor values are for design guidance only:
These capacitors were tested with the resonators listed below for basic start-up and operation. **These values are not optimized.**
Different capacitor values may be required to produce acceptable oscillator operation. The user should test the performance of the oscillator over the expected VDD and temperature range for the application. See the notes following Table 3-6 for additional information.

**Resonators Used:**
- 4.0 MHz
- 8.0 MHz
- 16.0 MHz

### Table 3-6: Capacitor Selection for Crystal Oscillator

<table>
<thead>
<tr>
<th>Osc Type (1)(4)</th>
<th>Crystal Freq. (2)</th>
<th>Typical Capacitor Values Tested:</th>
</tr>

<td>4 MHz</td>
<td>27 pF</td>
</tr>
<tr>
<td></td>
<td>8 MHz</td>
<td>22 pF</td>
</tr>
<tr>
<td></td>
<td>20 MHz</td>
<td>15 pF</td>
</tr>
</tbody>
</table>

Capacitor values are for design guidance only:
These capacitors were tested with the crystals listed below for basic start-up and operation. **These values are not optimized.**
Different capacitor values may be required to produce acceptable oscillator operation. The user should test the performance of the oscillator over the expected VDD and temperature range for the application. See the notes following this table for additional information.

**Crystals Used (3):**
- 4.0 MHz
- 8.0 MHz
- 20.0 MHz

**Note 1:** While higher capacitance increases the stability of the oscillator, it also increases the start-up time.

2: Since each resonator/crystal has its own characteristics, the user should consult the resonator/crystal manufacturer for appropriate values of external components.

3: R_S may be required to avoid overdriving crystals with low drive level specification.

4: Always verify oscillator performance over the VDD and temperature range that is expected for the application.
3.14 Reset

The MCP25625 differentiates between two Resets:

1. Hardware Reset – Low on RESET pin
2. SPI Reset – Reset via SPI command (see Section 5.1 “RESET Instruction”)

Both of these Resets are functionally equivalent. It is important to provide one of these two Resets after power-up to ensure that the logic and registers are in their default state. A hardware Reset can be achieved automatically by placing an RC on the RESET pin (see Figure 3-16). The values must be such that the device is held in Reset for a minimum of 2 µs after VDD reaches the operating voltage, as indicated in the electrical specification (tRL).

FIGURE 3-16: RESET PIN CONFIGURATION EXAMPLE

Note 1: The diode, D, helps discharge the capacitor quickly when VDD powers down.
2: R1 = 1 kΩ to 10 kΩ will limit any current flowing into RESET from external capacitor, C, in the event of RESET pin breakdown due to Electrostatic Discharge (ESD) or Electrical Overstress (EOS).
4.0 REGISTER MAP

The register map for the MCP25625 is shown in Table 4-1. Address locations for each register are determined by using the column (higher order four bits) and row (lower order four bits) values. The registers have been arranged to optimize the sequential reading and writing of data. Some specific control and status registers allow individual bit modification using the SPI BIT MODIFY command. The registers that allow this command are shown as shaded locations in Table 4-1. A summary of the MCP25625 control registers is shown in Table 4-2.

- ‘-n’ = Value at POR  
- ‘1’ = Bit is set  
- ‘0’ = Bit is cleared  
- **x** = Bit is unknown  

- **Unimplemented**: Read as ‘0’

- **RXM[1:0]**: Receive Buffer Operating mode bits
  - 11 = Turns mask/filters off; receives any message  
  - 10 = Reserved  
  - 01 = Reserved  
  - 00 = Receives all valid messages using either Standard or Extended Identifiers that meet filter criteria; Extended ID Filter registers, RXFxEID8 and RXFxEID0, are applied to the first two bytes of data in the messages with standard IDs.

- **RXRTR**: Received Remote Transfer Request bit
  - 1 = Remote Transfer Request received  
  - 0 = No Remote Transfer Request received

- **BUKT**: Rollover Enable bit
  - 1 = RXB0 message will roll over and be written to RXB1 if RXB0 is full  
  - 0 = Rollover is disabled

- **BUKT1**: Read-Only Copy of BUKT bit (used internally by the MCP25625)

- **FILHIT0**: Filter Hit bit(1)

  Indicates which acceptance filter enabled the reception of a message.
  - 1 = Acceptance Filter 1 (RXF1)  
  - 0 = Acceptance Filter 0 (RXF0)

**Note 1:** If a rollover from RXB0 to RXB1 occurs, the FILHIT0 bit will reflect the filter that accepted the message that rolled over.

5.0 SPI INTERFACE

The MCP25625 is designed to interface directly with the Serial Peripheral Interface (SPI) port available on many microcontrollers and supports Mode 0,0 and Mode 1,1.

Commands and data are sent to the device via the SI pin, with data being clocked in on the rising edge of SCK. Data is driven out by the MCP25625 (on the SO line) on the falling edge of SCK. The CS pin must be held low while any operation is performed.

Table 5-1 shows the instruction bytes for all operations. Refer to Figures 5-10 and 5-11 for detailed input and output timing diagrams for both Mode 0,0 and Mode 1,1 operation.

Note 1: The MCP25625 expects the first byte, after lowering CS, to be the instruction/command byte. This implies that CS must be raised and then lowered again to invoke another command.

### TABLE 5-1: SPI INSTRUCTION SET

</tr>
<tr>
<td>BIT MODIFY</td>
<td>0000 0101</td>
<td>Allows the user to set or clear individual bits in a particular register.(2)</td>
</tr>
</tbody>
</table>

Note 1: The associated RX flag bit (RXxIF bits in the CANINTF register) will be cleared after bringing CS high.

2: Not all registers can be bit modified with this command. Executing this command on registers that are not bit modifiable will force the mask to FFh. See the register map in Section 4.0 “Register Map” for a list of the registers that apply.
5.1 **RESET Instruction**

The **RESET** instruction can be used to re-initialize the internal registers of the MCP25625 and set Configuration mode. This command provides the same functionality, via the SPI interface, as the **RESET** pin.

The **RESET** instruction is a single byte instruction that requires selecting the device by pulling **CS** low, sending the instruction byte and then raising **CS**. It is highly recommended that the **RESET** command be sent (or the **RESET** pin be lowered) as part of the power-on initialization sequence.

5.2 **READ Instruction**

The **READ** instruction is started by lowering the **CS** pin. The **READ** instruction is then sent to the MCP25625, followed by the 8-bit address (A7 through A0). Next, the data stored in the register at the selected address will be shifted out on the **SO** pin.

The internal Address Pointer is automatically incremented to the next address once each byte of data is shifted out. Therefore, it is possible to read the next consecutive register address by continuing to provide clock pulses. Any number of consecutive register locations can be read sequentially using this method. The **READ** operation is terminated by raising the **CS** pin (**Figure 5-2**).

5.3 **READ RX BUFFER Instruction**

The **READ RX BUFFER** instruction (**Figure 5-3**) provides a means to quickly address a receive buffer for reading. This instruction reduces the SPI overhead by one byte: the address byte. The command byte actually has four possible values that determine the Address Pointer location. Once the command byte is sent, the controller clocks out the data at the address location the same as the **READ** instruction (i.e., sequential reads are possible). This instruction further reduces the SPI overhead by automatically clearing the associated receive flag (RXXIF bit in the CANINTF register) when **CS** is raised at the end of the command.

5.4 **WRITE Instruction**

The **WRITE** instruction is started by lowering the **CS** pin. The **WRITE** instruction is then sent to the MCP25625, followed by the address and at least one byte of data.

It is possible to write to sequential registers by continuing to clock in data bytes, as long as **CS** is held low. Data will actually be written to the register on the rising edge of the **SCK** line for the D0 bit. If the **CS** line is brought high before eight bits are loaded, the write will be aborted for that data byte and previous bytes in the command will have been written. Refer to the timing diagram in **Figure 5-4** for a more detailed illustration of the byte **WRITE** sequence.

5.5 **LOAD TX BUFFER Instruction**

The **LOAD TX BUFFER** instruction (**Figure 5-5**) eliminates the 8-bit address required by a normal **WRITE** command. The 8-bit instruction sets the Address Pointer to one of six addresses to quickly write to a transmit buffer that points to the “ID” or “data” address of any of the three transmit buffers.

5.6 **Request-to-Send (RTS) Instruction**

The **RTS** command can be used to initiate message transmission for one or more of the transmit buffers.

The MCP25625 is selected by lowering the **CS** pin. The **RTS** command byte is then sent. Shown in **Figure 5-6**, the last three bits of this command indicate which transmit buffer(s) are enabled to send.

This command will set the TXREQ bit in the TXBxCTRL register for the respective buffer(s). Any or all of the last three bits can be set in a single command. If the **RTS** command is sent with nnn = 000, the command will be ignored.

5.7 **READ STATUS Instruction**

The **READ STATUS** instruction allows single instruction access to some of the often used Status bits for message reception and transmission.

The MCP25625 is selected by lowering the **CS** pin and the **READ STATUS** command byte, shown in **Figure 5-8**, is sent to the MCP25625. Once the command byte is sent, the MCP25625 will return eight bits of data that contain the status.

If additional clocks are sent after the first eight bits are transmitted, the MCP25625 will continue to output the Status bits as long as the **CS** pin is held low and clocks are provided on **SCK**.

Each Status bit returned in this command may also be read by using the standard **READ** command with the appropriate register address.

5.8 **RX STATUS Instruction**

The **RX STATUS** instruction (**Figure 5-9**) is used to quickly determine which filter matched the message and message type (standard, extended, remote). After the command byte is sent, the controller will return eight bits of data that contain the status data. If more clocks are sent after the eight bits are transmitted, the controller will continue to output the same Status bits as long as the **CS** pin stays low and clocks are provided.
5.9 BIT MODIFY Instruction

The BIT MODIFY instruction provides a means for setting or clearing individual bits in specific status and control registers. This command is not available for all registers. See Section 4.0 “Register Map” to determine which registers allow the use of this command.

Note: Executing the BIT MODIFY command on registers that are not bit-modifiable will force the mask to FFh. This will allow byte writes to the registers, not BIT MODIFY.

The part is selected by lowering the CS pin and the BIT MODIFY command byte is then sent to the MCP25625. The command is followed by the address of the register, the mask byte, and finally, the data byte. The mask byte determines which bits in the register will be allowed to change. A ‘1’ in the mask byte will allow a bit in the register to change, while a ‘0’ will not (see Figure 5-1).

The data byte determines what value the modified bits in the register will be changed to. A ‘1’ in the data byte will set the bit and a ‘0’ will clear the bit, provided that the mask for that bit is set to a ‘1’ (see Figure 5-7).

FIGURE 5-10: SPI INPUT TIMING

FIGURE 5-11: SPI OUTPUT TIMING
6.0 CAN TRANSCEIVER

The CAN transceiver is a differential, high-speed, Fault tolerant interface to the CAN physical bus. It is fully compatible with the ISO-11898-2 and ISO-11898-5 standards. It operates at speeds of up to 1 Mb/s.

The CAN transceiver converts the digital TxCAN signal generated by the CAN controller to signals suitable for transmission over the physical CAN bus (differential output). It also translates the differential CAN bus voltage to the RxCAN input signal of the CAN controller.

The CAN transceiver meets the stringent automotive EMC and ESD requirements.

Figure 6-1 illustrates the block diagram of the CAN transceiver.

FIGURE 6-1: CAN TRANSCEIVER BLOCK DIAGRAM
6.1 Transmitter Function

The CAN bus has two states: Dominant and Recessive. A Dominant state occurs when the differential voltage between CANH and CANL is greater than $V_{\text{DIFF(D)}}$. A Recessive state occurs when the differential voltage is less than $V_{\text{DIFF(R)}}$. The Dominant and Recessive states correspond to the low and high state of the $T_XD$ input pin, respectively. However, a Dominant state initiated by another CAN node will override a Recessive state on the CAN bus.

6.2 Receiver Function

In Normal mode, the $R_XD$ output pin reflects the differential bus voltage between CANH and CANL. The low and high states of the $R_XD$ output pin correspond to the Dominant and Recessive states of the CAN bus, respectively.

6.3 Internal Protection

CANH and CANL are protected against battery short circuits and electrical transients that can occur on the CAN bus. This feature prevents destruction of the transmitter output stage during such a Fault condition. The device is further protected from excessive current loading by thermal shutdown circuitry that disables the output drivers when the junction temperature exceeds a nominal limit of $+175^\circ\text{C}$. All other parts of the chip remain operational and the chip temperature is lowered due to the decreased power dissipation in the transmitter outputs. This protection is essential to protect against bus line short-circuit induced damage.

6.4 Permanent Dominant Detection

The CAN transceiver device prevents two conditions:
- Permanent Dominant condition on $T_XD$
- Permanent Dominant condition on the bus

In Normal mode, if the CAN transceiver detects an extended low state on the $T_XD$ input, it will disable the CANH and CANL output drivers in order to prevent the corruption of data on the CAN bus. The drivers will remain disabled until $T_XD$ goes high.

In Standby mode, if the CAN transceiver detects an extended Dominant condition on the bus, it will set the $R_XD$ pin to the Recessive state. This allows the attached controller to go to Low-Power mode until the Dominant issue is corrected. $R_XD$ is latched high until a Recessive state is detected on the bus and the wake-up function is enabled again.

Both conditions have a time-out of 1.25 ms (typical). This implies a maximum bit time of 69.44 $\mu\text{s}$ (14.4 kHz), allowing up to 18 consecutive Dominant bits on the bus.

6.5 Power-on Reset (POR) and Undervoltage Detection

The MCP25625 has undervoltage detection on both supply pins: $V_{\text{DDA}}$ and $V_{\text{IO}}$. Typical undervoltage thresholds are 1.2V for $V_{\text{IO}}$ and 4V for $V_{\text{DDA}}$.

When the device is powered on, CANH and CANL remain in a high-impedance state until both $V_{\text{DDA}}$ and $V_{\text{IO}}$ exceed their undervoltage levels. In addition, CANH and CANL will remain in a high-impedance state if $T_XD$ is low when both undervoltage thresholds are reached. CANH and CANL will become active only after $T_XD$ is asserted high. Once powered on, CANH and CANL will enter a high-impedance state if the voltage level at $V_{\text{DDA}}$ drops below the undervoltage level, providing voltage brown-out protection during normal operation.

In Normal mode, the receiver output is forced to a Recessive state during an undervoltage condition on $V_{\text{DDA}}$. In Standby mode, the low-power receiver is only enabled when both $V_{\text{DDA}}$ and $V_{\text{IO}}$ supply voltages rise above their respective undervoltage thresholds. Once these threshold voltages are reached, the low-power receiver is no longer controlled by the POR comparator and remains operational down to about 2.5V on the $V_{\text{DDA}}$ supply. The CAN transceiver transfers data to the $R_XD$ pin down to 1V on the $V_{\text{IO}}$ supply.

6.6 Pin Description

6.6.1 TRANSMITTER DATA INPUT PIN ($T_XD$)

The CAN transceiver drives the differential output pins, CANH and CANL, according to $T_XD$. The transceiver is connected to the $T_xCAN$ pin of the CAN controller. When $T_XD$ is low, CANH and CANL are in the Dominant state. When $T_XD$ is high, CANH and CANL are in the Recessive state, provided that another CAN node is not driving the CAN bus with a Dominant state. $T_XD$ is connected to an internal pull-up resistor (nominal 33 $k\Omega$) to $V_{\text{IO}}$.

6.6.2 GROUND SUPPLY PIN ($V_{\text{SS}}$)

Ground supply pin.

6.6.3 SUPPLY VOLTAGE PIN ($V_{\text{DDA}}$)

Positive supply voltage pin. Supplies transmitter and receiver, including the wake-up receiver.
6.6.4 RECEIVER DATA OUTPUT PIN (RXD)
RXD is a CMOS compatible output that drives high or low depending on the differential signals on the CANH and CANL pins, and is usually connected to the receiver data input of the CAN controller device. RXD is high when the CAN bus is Recessive and low in the Dominant state. RXD is supplied by VIO.

6.6.5 VIO PIN
Supply for digital I/O pins of the CAN transceiver.

6.6.6 CAN LOW PIN (CANL)
The CANL output drives the low side of the CAN differential bus. This pin is also tied internally to the receive input comparator. CANL disconnects from the bus when VDDA is not powered.

6.6.7 CAN HIGH PIN (CANH)
The CANH output drives the high side of the CAN differential bus. This pin is also tied internally to the receive input comparator. CANH disconnects from the bus when VDDA is not powered.

6.6.8 STANDBY MODE INPUT PIN (STBY)
This pin selects between Normal or Standby mode of the CAN transceiver. In Standby mode, the transmitter and the high-speed receiver are turned off, only the low-power receiver and wake-up filter are active. STBY is connected to an internal MOS pull-up resistor to VIO. The value of the MOS pull-up resistor depends on the supply voltage. Typical values are 660 kΩ for 5V, 1.1 MΩ for 3.3V and 4.4 MΩ for 1.8V.

6.6.9 EXPOSED THERMAL PAD (EP)
It is recommended to connect this pad to VSS to enhance electromagnetic immunity and thermal resistance.

Virtual Junction Temperature, T_{VJ} (IEC60747-1) ...................................................................................................-40°C to +150°C
Soldering Temperature of Leads (10 seconds) ................................................................................................................+300°C
ESD Protection on CANH and CANL Pins (IEC 61000-4-2) ..................................................................................±8 kV
ESD Protection on CANH and CANL Pins (IEC 801; Human Body Model) .................................................................±8 kV
ESD Protection on All Other Pins (IEC 801; Human Body Model) ................................................................................±4 kV
ESD Protection on All Pins (IEC 801; Machine Model) .................................................................................................±300V
ESD Protection on All Pins (IEC 801; Charge Device Model) .......................................................................................±750V

† NOTICE: Stresses above those listed under “Maximum ratings” may cause permanent damage to the device. This is a stress rating only and functional operation of the device at those or any other conditions above those indicated in the operational listings of this specification is not implied. Exposure to maximum rating conditions for extended periods may affect device reliability.

</table>

7.5 Terms and Definitions

A number of terms are defined in ISO-11898 that are used to describe the electrical characteristics of a CAN transceiver device. These terms and definitions are summarized in this section.

7.5.1 BUS VOLTAGE

\( V_{CANL} \) and \( V_{CANH} \) denote the voltages of the bus line wires, CANL and CANH, relative to the ground of each individual CAN node.

7.5.2 COMMON-MODE BUS VOLTAGE RANGE

Boundary voltage levels of \( V_{CANL} \) and \( V_{CANH} \), with respect to ground for which proper operation will occur, if up to the maximum number of CAN nodes are connected to the bus.

7.5.3 DIFFERENTIAL INTERNAL CAPACITANCE, \( C_{DIFF} \)

OF A CAN NODE

Capacitance seen between CANL and CANH during the Recessive state when the CAN node is disconnected from the bus (see Figure 7-10).

7.5.4 DIFFERENTIAL INTERNAL RESISTANCE, \( R_{DIFF} \)

OF A CAN NODE

Resistance seen between CANL and CANH during the Recessive state when the CAN node is disconnected from the bus (see Figure 7-10).

7.5.5 DIFFERENTIAL VOLTAGE, \( V_{DIFF} \)

OF CAN BUS

Differential voltage of the two-wire CAN bus, value: \( V_{DIFF} = V_{CANH} - V_{CANL} \).

7.5.6 INTERNAL CAPACITANCE, \( C_{IN} \)

OF A CAN NODE

Capacitance seen between CANL (or CANH) and ground, during the Recessive state, when the CAN node is disconnected from the bus (see Figure 7-10).

7.5.7 INTERNAL RESISTANCE, \( R_{IN} \)

OF A CAN NODE

Resistance seen between CANL (or CANH) and ground, during the Recessive state, when the CAN node is disconnected from the bus (see Figure 7-10).

8.0 PACKAGING INFORMATION

8.1 Package Marking Information

Legend:

- **XX...X** Customer-specific information
- **Y** Year code (last digit of calendar year)
- **YY** Year code (last 2 digits of calendar year)
- **WW** Week code (week of January 1 is week ‘01’)
- **NNN** Alphanumeric traceability code
- **e3** Pb-free JEDEC® designator for Matte Tin (Sn)
- **(*)** This package is Pb-free. The Pb-free JEDEC designator (e3) can be found on the outer packaging for this package.

Example:

28-Lead QFN (6x6 mm)

- XXXXXXXXX
- XXXXXXXXX
- YYWWNNN

MCP25625 E/ML(e3)

1644256

28-Lead SSOP (5.30 mm)

- XXXXXXXXXXXX
- XXXXXXXXXXXX
- YYWWNNN

MCP25625 E/SS(e3)

1644256

Note: In the event the full Microchip part number cannot be marked on one line, it will be carried over to the next line, thus limiting the number of available characters for customer-specific information.
MCP25625

28-Lead Plastic Quad Flat, No Lead Package (ML) - 6x6 mm Body [QFN] With 0.55 mm Terminal Length

APPENDIX A:  REVISION HISTORY

Revision C (January 2019)
The following is the list of modifications:
1. Updated Figure 1-2.
2. Updated Section 3.13.1, Oscillator Start-up Timer.
3. Updated Table 4-2.
4. Updated Register 4-34.

Revision B (January 2017)
The following is the list of modifications:
1. The usage of the RXMx bits setting, '01' and '10', in the RXBxCTRL registers (Register 4-9 and Register 4-10) is not recommended.
2. Updated Figure 3-11.
3. Updated Table 3-3.

Revision A (March 2014)
• Original Release of this Document.
# PRODUCT IDENTIFICATION SYSTEM

To order or obtain information, e.g., on pricing or delivery, refer to the factory or the listed sales office.

<th>/XX</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device</td>
<td>Tape and Reel Option</td>
<td>Temperature Range</td>
<td>Package</td>
</tr>
</tbody>
</table>

**Device:** MCP25625 CAN Controller with Integrated Transceiver

**Temperature Range:**

- **E** = -40°C to +125°C (Extended)

**Tape and Reel Option:**

- **Blank** = Standard packaging (tube)
- **T** = Tape and Reel

**Package:**

- **ML** = Plastic Quad Flat, No Lead Package – 6x6 mm Body with 0.55 mm Terminal Length, 28-Lead
- **SS** = Plastic Shrink Small Outline – 5.30 mm Body 28-Lead

### Examples:

a) MCP25625-E/ML: Extended Temperature, 28-Lead 6x6 QFN Package

b) MCP25625-E/SS: Extended Temperature, 28-Lead SSOP Package

c) MCP25625T-E/ML: Tape and Reel, Extended Temperature, 28-Lead 6x6 QFN Package

d) MCP25625T-E/SS: Tape and Reel, Extended Temperature, 28-Lead SSOP Package

**Note 1:** Tape and Reel identifier only appears in the catalog part number description. This identifier is used for ordering purposes and is not printed on the device package. Check with your Microchip Sales Office for package availability with the Tape and Reel option.
Note the following details of the code protection feature on Microchip devices:

- Microchip products meet the specification contained in their particular Microchip Data Sheet.
- Microchip believes that its family of products is one of the most secure families of its kind on the market today, when used in the intended manner and under normal conditions.
- There are dishonest and possibly illegal methods used to breach the code protection feature. All of these methods, to our knowledge, require using the Microchip products in a manner outside the operating specifications contained in Microchip’s Data Sheets. Most likely, the person doing so is engaged in theft of intellectual property.
- Microchip is willing to work with the customer who is concerned about the integrity of their code.
- Neither Microchip nor any other semiconductor manufacturer can guarantee the security of their code. Code protection does not mean that we are guaranteeing the product as “unbreakable.”

Code protection is constantly evolving. We at Microchip are committed to continuously improving the code protection features of our products. Attempts to break Microchip’s code protection feature may be a violation of the Digital Millennium Copyright Act. If such acts allow unauthorized access to your software or other copyrighted work, you may have a right to sue for relief under that Act.

Information contained in this publication regarding device applications and the like is provided only for your convenience and may be superseded by updates. It is your responsibility to ensure that your application meets with your specifications. MICROCHIP MAKES NO REPRESENTATIONS OR WARRANTIES OF ANY KIND WHETHER EXPRESS OR IMPLIED, WRITTEN OR ORAL, STATUTORY OR OTHERWISE, RELATED TO THE INFORMATION, INCLUDING BUT NOT LIMITED TO ITS CONDITION, QUALITY, PERFORMANCE, MERCHANTABILITY OR FITNESS FOR PURPOSE. Microchip disclaims all liability arising from this information and its use. Use of Microchip devices in life support and/or safety applications is entirely at the buyer’s risk, and the buyer agrees to defend, indemnify and hold harmless Microchip from any and all damages, claims, suits, or expenses resulting from such use. No licenses are conveyed, implicitly or otherwise, under any Microchip intellectual property rights unless otherwise stated.

Trademarks
The Microchip name and logo, the Microchip logo, AnyRate, AVR, AVR logo, AVR Freaks, BitCloud, chipKIT, chipKIT logo, CryptoMemory, CryptoRF, dsPIC, FlashFlex, flexPWR, Heldo, JukeBox, KeeLoq, Kleer, LANCheck, LINK MD, maxXSylus, mxTouch, MediaLB, megaAVR, MOST, MOST logo, MPLAB, OptoLyzer, PIC, picoPower, PICSTART, PIC32 logo, Prochip Designer, QTouch, SAM-BA, SpyNic, SST, SST Logo, SuperFlash, tinyAVR, UNI/O, and XMEGA are registered trademarks of Microchip Technology Incorporated in the U.S.A. and other countries.

Microchip received ISO/TS-16949:2009 certification for its worldwide headquarters, design and wafer fabrication facilities in Chandler and Tempe, Arizona; Gresham, Oregon and design centers in California and India. The company’s quality system processes and procedures are for its PIC® MCUs and dsPIC® DSCs, KeeLoq® code hopping devices, Serial EEPROMs, microperipherals, nonvolatile memory and analog products. In addition, Microchip’s quality system for the design and manufacture of development systems is ISO 9001:2000 certified.
