MIC28510
75V/4A Hyper Speed Control™
Synchronous DC/DC Buck Regulator

SuperSwitcher II™

General Description
The Micrel MIC28510 is an adjustable–frequency, synchronous buck regulator featuring unique adaptive on–time control architecture. The MIC28510 operates over an input supply range of 4.5V to 75V and provides a regulated output of up to 4A of output current. The output voltage is adjustable down to 0.8V with a guaranteed accuracy of ±1%.

Micrel's Hyper Speed Control™ architecture allows for ultra–fast transient response while reducing the output capacitance and also makes (High VIN) / (Low VOUT) operation possible. This adaptive tON ripple control architecture combines the advantages of fixed–frequency operation and fast transient response in a single device.

The MIC28510 offers a full suite of protection features to ensure protection of the IC during fault conditions. These include undervoltage lockout to ensure proper operation under power–sag conditions, internal soft–start to reduce inrush current, foldback current limit, “hiccup” mode short-circuit protection, and thermal shutdown.

All support documentation can be found on Micrel's web site at: www.micrel.com.

Features
- Hyper Speed Control™ architecture enables:
  - High Delta V operation (VIN = 75V and VOUT = 0.8V)
  - Small output capacitance
- 4.5V to 75V voltage input
- 4A output current capability, up to 95% efficiency
- Adjustable output voltage form 0.8V to 24V
- ±1% FB accuracy
- Any Capacitor™ stable:
  - Zero-ESR to high–ESR output capacitors
- 100kHz to 500kHz switching frequency
- Internal compensation
- Foldback current–limit and “hiccup” mode short-circuit protection
- Thermal shutdown
- Supports safe startup into a pre–biased load
- −40°C to +125°C junction temperature range
- 28-pin 5mm × 6mm MLF® package

Applications
- Distributed power systems
- Communications/networking infrastructure
- Industrial power
- Solar energy

Typical Application

Hyper Speed Control, SuperSwitcher II and Any Capacitor are trademarks of Micrel, Inc.
MLF and MicroLeadFrame are registered trademarks of Amkor Technology, Inc.

Notes:
1. Exceeding the absolute maximum rating may damage the device.
2. Devices are ESD sensitive. Handling precautions recommended. Human body model, 1.5kΩ in series with 100pF.
3. The device is not guaranteed to function outside operating range.
4. PD\(_{\text{MAX}}\) = (T\(_{\text{JMAX}}\) – T\(_{\text{A}}\))/\(\theta_{\text{JA}}\), where \(\theta_{\text{JA}}\) depends upon the printed circuit layout. See “Applications Information.”
5. Specification for packaged product only.

Figure 1. MIC28510 Block Diagram
**Functional Description**

The MIC28510 is an adaptive ON-time synchronous step-down DC/DC regulator. It is designed to operate over a wide input voltage range from 4.5V to 75V, and provides a regulated output voltage at up to 4A of output current. A digitally-modified adaptive ON-time control scheme is employed in order to obtain a constant-switching frequency and to simplify the control compensation. Over current protection is implemented without the use of an external sense resistor. The device includes an internal soft-start function which reduces the power supply input surge current at start-up by controlling the output voltage rise time.

**Theory of Operation**

Figure 1 illustrates the block diagram for the control loop of the MIC28510. The output voltage is sensed by the MIC28510 feedback pin FB via the voltage divider R1 and R2, and compared to a 0.8V reference voltage V_REF at the error comparator through a low–gain transconductance (g_m) amplifier. If the feedback voltage decreases and the output of the g_m amplifier is below 0.8V, then the error comparator will trigger the control logic and generate an ON–time period. The ON–time period length is predetermined by the “FIXED t_ON ESTIMATION” circuitry:

\[
\text{t}_{\text{ON(estimated)}} = \frac{V_{\text{OUT}}}{V_{\text{IN}} \times f_{\text{SW}}} \quad \text{Eq. 1}
\]

where \(V_{\text{OUT}}\) is the output voltage and \(V_{\text{IN}}\) is the power stage input voltage and \(f_{\text{SW}}\) is the switching frequency.

At the end of the ON–time period, the internal high–side driver turns off the high–side MOSFET and the low–side driver turns on the low–side MOSFET. The OFF–time period length depends upon the feedback voltage in most cases. When the feedback voltage decreases and the output of the g_m amplifier is below 0.8V, the ON-time period is triggered and the OFF–time period ends. If the OFF–time period determined by the feedback voltage is less than the minimum OFF–time \(t_{\text{OFF(MIN)}}\), which is about 360ns, then the MIC28510 control logic will apply the \(t_{\text{OFF(MIN)}}\) instead. The minimum \(t_{\text{OFF(MIN)}}\) period is required to maintain enough energy in the boost capacitor (\(C_{\text{BST}}\)) to drive the high–side MOSFET.

The actual ON–time and resulting switching frequency will vary with the part–to–part variation in the rise and fall times of the internal MOSFETs, the output load current, and variations in the \(V_{\text{DD}}\) voltage. Also, the minimum \(t_{\text{ON}}\) results in a lower switching frequency in high \(V_{\text{IN}}\) to \(V_{\text{OUT}}\) applications, such as 75V to 1.0V.

Figure 2 shows the MIC28510 control loop timing during steady-state operation. During steady-state, the g_m amplifier senses the feedback voltage ripple, which is proportional to the output voltage ripple and the inductor current ripple, to trigger the ON–time period. The ON–time is predetermined by the t_ON estimator. The termination of the OFF–time is controlled by the feedback voltage. At the valley of the feedback voltage ripple, which occurs when \(V_{\text{FB}}\) falls below \(V_{\text{REF}}\), the OFF period ends and the next ON–time period is triggered through the control logic circuitry.

The maximum duty cycle is obtained from the 360ns \(t_{\text{OFF(MIN)}}\):

\[
D_{\text{MAX}} = \frac{t_{\text{S}} - t_{\text{OFF(MIN)}}}{t_{\text{S}}} = 1 - \frac{360\text{ns}}{t_{\text{S}}} \quad \text{Eq. 2}
\]

where \(t_{\text{S}} = 1/f_{\text{SW}}\). It is not recommended to use MIC28510 with an OFF-time close to \(t_{\text{OFF(MIN)}}\) during steady-state operation.

The actual ON–time and resulting switching frequency will vary with the part–to–part variation in the rise and fall times of the internal MOSFETs, the output load current, and variations in the \(V_{\text{DD}}\) voltage. Also, the minimum \(t_{\text{ON}}\) results in a lower switching frequency in high \(V_{\text{IN}}\) to \(V_{\text{OUT}}\) applications, such as 75V to 1.0V.

Figure 2 shows the MIC28510 control loop timing during steady-state operation. During steady-state, the g_m amplifier senses the feedback voltage ripple, which is proportional to the output voltage ripple and the inductor current ripple, to trigger the ON–time period. The ON–time is predetermined by the t_ON estimator. The termination of the OFF–time is controlled by the feedback voltage. At the valley of the feedback voltage ripple, which occurs when \(V_{\text{FB}}\) falls below \(V_{\text{REF}}\), the OFF period ends and the next ON–time period is triggered through the control logic circuitry.

The maximum duty cycle is obtained from the 360ns \(t_{\text{OFF(MIN)}}\):

\[
D_{\text{MAX}} = \frac{t_{\text{S}} - t_{\text{OFF(MIN)}}}{t_{\text{S}}} = 1 - \frac{360\text{ns}}{t_{\text{S}}} \quad \text{Eq. 2}
\]

where \(t_{\text{S}} = 1/f_{\text{SW}}\). It is not recommended to use MIC28510 with an OFF-time close to \(t_{\text{OFF(MIN)}}\) during steady-state operation.

The actual ON–time and resulting switching frequency will vary with the part–to–part variation in the rise and fall times of the internal MOSFETs, the output load current, and variations in the \(V_{\text{DD}}\) voltage. Also, the minimum \(t_{\text{ON}}\) results in a lower switching frequency in high \(V_{\text{IN}}\) to \(V_{\text{OUT}}\) applications, such as 75V to 1.0V.

Figure 2 shows the MIC28510 control loop timing during steady-state operation. During steady-state, the g_m amplifier senses the feedback voltage ripple, which is proportional to the output voltage ripple and the inductor current ripple, to trigger the ON–time period. The ON–time is predetermined by the t_ON estimator. The termination of the OFF–time is controlled by the feedback voltage. At the valley of the feedback voltage ripple, which occurs when \(V_{\text{FB}}\) falls below \(V_{\text{REF}}\), the OFF period ends and the next ON–time period is triggered through the control logic circuitry.

The maximum duty cycle is obtained from the 360ns \(t_{\text{OFF(MIN)}}\):

\[
D_{\text{MAX}} = \frac{t_{\text{S}} - t_{\text{OFF(MIN)}}}{t_{\text{S}}} = 1 - \frac{360\text{ns}}{t_{\text{S}}} \quad \text{Eq. 2}
\]

where \(t_{\text{S}} = 1/f_{\text{SW}}\). It is not recommended to use MIC28510 with an OFF-time close to \(t_{\text{OFF(MIN)}}\) during steady-state operation.

The actual ON–time and resulting switching frequency will vary with the part–to–part variation in the rise and fall times of the internal MOSFETs, the output load current, and variations in the \(V_{\text{DD}}\) voltage. Also, the minimum \(t_{\text{ON}}\) results in a lower switching frequency in high \(V_{\text{IN}}\) to \(V_{\text{OUT}}\) applications, such as 75V to 1.0V.

Figure 2 shows the MIC28510 control loop timing during steady-state operation. During steady-state, the g_m amplifier senses the feedback voltage ripple, which is proportional to the output voltage ripple and the inductor current ripple, to trigger the ON–time period. The ON–time is predetermined by the t_ON estimator. The termination of the OFF–time is controlled by the feedback voltage. At the valley of the feedback voltage ripple, which occurs when \(V_{\text{FB}}\) falls below \(V_{\text{REF}}\), the OFF period ends and the next ON–time period is triggered through the control logic circuitry.

The maximum duty cycle is obtained from the 360ns \(t_{\text{OFF(MIN)}}\):

\[
D_{\text{MAX}} = \frac{t_{\text{S}} - t_{\text{OFF(MIN)}}}{t_{\text{S}}} = 1 - \frac{360\text{ns}}{t_{\text{S}}} \quad \text{Eq. 2}
\]

where \(t_{\text{S}} = 1/f_{\text{SW}}\). It is not recommended to use MIC28510 with a OFF-time close to \(t_{\text{OFF(MIN)}}\) during steady-state operation.

The actual ON–time and resulting switching frequency will vary with the part–to–part variation in the rise and fall times of the internal MOSFETs, the output load current, and variations in the \(V_{\text{DD}}\) voltage. Also, the minimum \(t_{\text{ON}}\) results in a lower switching frequency in high \(V_{\text{IN}}\) to \(V_{\text{OUT}}\) applications, such as 75V to 1.0V.
Figure 3 shows the operation of the MIC28510 during load transient. The output voltage drops due to the sudden load increase, which causes the $V_{FB}$ to be less than $V_{REF}$. This will cause the error comparator to trigger an ON–time period. At the end of the ON–time period, a minimum OFF–time $t_{OFF(min)}$ is generated to charge $C_{BST}$ since the feedback voltage is still below $V_{REF}$. Then, the next ON–time period is triggered due to the low feedback voltage. Therefore, the switching frequency changes during the load transient, but returns to the nominal fixed frequency once the output has stabilized at the new load current level. With the varying duty cycle and switching frequency, the output recovery time is fast and the output voltage deviation is small in MIC28510 converter.

Unlike true current–mode control, the MIC28510 uses the output voltage ripple to trigger an ON–time period. The output voltage ripple is proportional to the inductor current ripple if the ESR of the output capacitor is large enough.

In order to meet the stability requirements, the MIC28510 feedback voltage ripple should be in phase with the inductor current ripple. The recommended feedback voltage ripple is 20mV~100mV. If a low–ESR output capacitor is selected, then the feedback voltage ripple may be too small to be sensed by the $g_m$ amplifier and the error comparator. Also, the output voltage ripple and the feedback voltage ripple are not necessarily in phase with the inductor current ripple if the ESR of the output capacitor is very low. In these cases, ripple injection is required to ensure proper operation. Please refer to “Ripple Injection” subsection in Application Information of this datasheet for more details regarding the ripple injection technique.

Soft–Start
Soft–start reduces the power supply input surge current at startup by controlling the output voltage rise time. The input surge appears while the output capacitor is charged up. A slower output rise time will draw a lower input surge current.

The MIC28510 implements an internal digital soft–start by making the 0.8V reference voltage $V_{REF}$ ramp from 0 to 100% in approximately 6ms with 9.7mV steps. Therefore, the output voltage is controlled to increase slowly with a stair–case $V_{FB}$ ramp. Once the soft–start cycle ends, the related circuitry is disabled to reduce current consumption. $V_{DD}$ must be powered up at the same time or after $V_{IN}$ to allow the soft–start function correctly.

Current Limit
The MIC28510 uses the $R_{DS(ON)}$ of the internal low–side power MOSFET to sense over–current conditions. This method will avoid adding cost, use of additional board space and power losses taken by a discrete current sense resistor.

In each switching cycle of the MIC28510 converter, the inductor current is sensed by monitoring the low–side MOSFET in the OFF period. If the peak inductor current is greater than 7A, then the MIC28510 turns off the high–side MOSFET and a soft–start sequence is triggered. This mode of operation is called “hiccup mode” and its purpose is to protect the downstream load in case of a hard short. The current–limit threshold has a foldback characteristic related to the feedback voltage, as shown in Figure 4.

![Figure 4. MIC28510 Current–Limit Foldback Characteristic](image-url)
Internal MOSFET Gate Drive

Figure 1 (the block diagram) shows a bootstrap circuit, consisting of D1 (a Schottky diode is recommended) and a capacitor connected from the SW pin to the BST pin ($C_{BST}$). This circuit supplies energy to the high–side drive circuit. Capacitor $C_{BST}$ is charged, while the low–side MOSFET is on, and the voltage on the SW pin is approximately 0V. When the high–side MOSFET driver is turned on, energy from $C_{BST}$ is used to turn the MOSFET on. As the high–side MOSFET turns on, the voltage on the SW pin increases to approximately $V_{IN}$. Diode D1 is reverse biased and $C_{BST}$ floats high while continuing to keep the high–side MOSFET on. The bias current of the high–side driver is less than 10mA so a 0.1μF to 1μF is sufficient to hold the gate voltage with minimal droop for the power stroke (high–side switching) cycle, i.e. $\Delta BST = 10mA \times 4\mu s/0.1\mu F = 400mV$. When the low–side MOSFET is turned back on, $C_{BST}$ is recharged through D1. A small resistor in series with $C_{BST}$, can be used to slow down the turn–on time of the high–side N–channel MOSFET.

The drive voltage is derived from the $PV_{DD}$ supply voltage. The nominal low–side gate drive voltage is $PV_{DD}$ and the nominal high–side gate drive voltage is approximately $PV_{DD} - V_{DIODE}$, where $V_{DIODE}$ is the voltage drop across D1. An approximate 30ns delay between the high–side and low–side driver transitions is used to prevent current from simultaneously flowing unimpeded through both MOSFETs.
Application Information

Setting the Switching Frequency

The MIC28510 is an adjustable-frequency, synchronous buck regulator featuring a unique digitally-modified, adaptive on-time control architecture. The switching frequency can be adjusted between 100kHz and 500kHz by changing the resistor divider network consisting of R18 and R19.

The following formula gives the estimated switching frequency:

$$f_{SW_{-}ADJ} = f_O \times \frac{R_{19}}{R_{18} + R_{19}}$$

where \( f_O \) = switching frequency when R18 is 100k and R19 being open, \( f_O \) is typically 450kHz. For more precise setting, it is recommended to use the graph illustrated in Figure 6:

Inductor Selection

Values for inductance, peak, and RMS currents are required to select the output inductor. The input and output voltages and the inductance value determine the peak–to–peak inductor ripple current. Generally, higher inductance values are used with higher input voltages. Larger peak–to–peak ripple currents will increase the power dissipation in the inductor and MOSFETs. Larger output ripple currents will also require more output capacitance to smooth out the larger ripple current. Smaller peak–to–peak ripple currents require a larger inductance value and therefore a larger and more expensive inductor. A good compromise between size, loss and cost is to set the inductor ripple current to be equal to 20% of the maximum output current. The inductance value is calculated by Equation 4:

$$L = \frac{V_{OUT} \times (V_{IN_{(max)}} - V_{OUT})}{V_{IN_{(max)}} \times f_{SW} \times 20\% \times I_{OUT_{(max)}}}$$

where:
- \( f_{SW} \) = Switching frequency
- \( 20\% \) = Ratio of AC ripple current to DC output current
- \( V_{IN_{(MAX)}} \) = Maximum power stage input voltage

The peak-to-peak inductor current ripple is:

$$\Delta L_{(pp)} = \frac{V_{OUT} \times (V_{IN_{(max)}} - V_{OUT})}{V_{IN_{(max)}} \times f_{SW} \times L}$$

The peak inductor current is equal to the average output current plus one half of the peak–to–peak inductor current ripple.

$$I_{L(pk)} = I_{OUT_{(max)}} + 0.5 \times \Delta L_{(pp)}$$

The RMS inductor current is used to calculate the \( i^2R \) losses in the inductor:

$$I_{L(RMS)} = \sqrt{I_{OUT_{(max)}}^2 + \frac{\Delta L_{(PP)}^2}{12}}$$
Maximizing efficiency requires the proper selection of core material while minimizing the winding resistance. The high frequency operation of the MIC28510 requires the use of ferrite materials for all but the most cost sensitive applications. Lower cost iron powder cores may be used but the increase in core loss will reduce the efficiency of the power supply. This is especially noticeable at low output power. The winding resistance decreases efficiency at the higher output current levels. The winding resistance must be minimized although this usually comes at the expense of a larger inductor. The power dissipated in the inductor is equal to the sum of the core and copper losses. At higher output loads, the core losses are usually insignificant and can be ignored. At lower output currents, the core losses can be a significant contributor. Core loss information is usually available from the magnetics vendor. Copper loss in the inductor is calculated by Equation 8:

\[ P_{\text{INDUCTOR(Cu)}} = I_{(\text{RMS})}^2 \times R_{\text{WINDING}} \] Eq. 8

The resistance of the copper wire, \( R_{\text{WINDING}} \), increases with the temperature. The value of the winding resistance used should be at the operating temperature:

\[ P_{\text{WINDING(Hi)}} = R_{\text{WINDING}(20^\circ C)} \times (1 + 0.0042 \times (T_H - T_{20^\circ C})) \] Eq. 9

where:

\( T_H \) = Temperature of wire under full load
\( T_{20^\circ C} \) = Ambient temperature
\( R_{\text{WINDING}(20^\circ C)} \) = Room temperature winding resistance (usually specified by the manufacturer)

**Output Capacitor Selection**

The type of the output capacitor is usually determined by its equivalent series resistance (ESR). Voltage and RMS current capability are two other important factors for selecting the output capacitor. Recommended capacitor types are ceramic, low–ESR aluminum electrolytic, OS–CON and POSCAP. The output capacitor’s ESR is usually the main cause of the output ripple. The output capacitor ESR also affects the control loop from a stability point of view.

The maximum value of ESR is calculated:

\[ ESR_{\text{Cout}} \leq \frac{\Delta V_{\text{OUT(pp)}}}{\Delta I_{L(PP)}} \] Eq. 10

where:

\( \Delta V_{\text{OUT(pp)}} \) = peak–to–peak output voltage ripple
\( \Delta I_{L(PP)} \) = peak–to–peak inductor current ripple

The total output ripple is a combination of the ESR and output capacitance. The total ripple is calculated in Equation 10:

\[ \Delta V_{\text{OUT(pp)}} = \sqrt{ \left( \frac{\Delta I_{L(PP)}}{C_{\text{OUT}} \times f_{\text{SW}} \times 8} \right)^2 + \left( \Delta I_{L(PP)} \times ESR_{\text{Cout}} \right)^2 } \] Eq. 11

where:

\( C_{\text{OUT}} \) = Output capacitance value
\( f_{\text{SW}} \) = Switching frequency

As described in the “Theory of Operation” subsection in Functional Description, the MIC28510 requires at least 20mV peak–to–peak ripple at the FB pin to make the \( g_m \) amplifier and the error comparator behave properly. Also, the output voltage ripple should be in phase with the inductor current. Therefore, the output voltage ripple caused by the output capacitors value should be much smaller than the ripple caused by the output capacitor ESR. If low–ESR capacitors, such as ceramic capacitors, are selected as the output capacitors, a ripple injection method should be applied to provide the enough feedback voltage ripple. Please refer to the “Ripple Injection” subsection for more details.

The voltage rating of the capacitor should be 20% greater for aluminum electrolytic or OS–CON. The output capacitor RMS current is calculated in Equation 12:

\[ I_{\text{Cout(RMS)}} = \frac{\Delta I_{L(PP)}}{\sqrt{12}} \] Eq. 12

The power dissipated in the output capacitor is:

\[ P_{\text{Diss(Cout)}} = I_{\text{Cout(RMS)}}^2 \times ESR_{\text{Cout}} \] Eq. 13
Input Capacitor Selection
The input capacitor for the power stage input $V_{IN}$ should be selected for ripple current rating and voltage rating. Tantalum input capacitors may fail when subjected to high inrush currents, caused by turning the input supply on. A tantalum input capacitor’s voltage rating should be at least two times the maximum input voltage to maximize reliability. Aluminum electrolytic, OS–CON, and multilayer polymer film capacitors can handle the higher inrush currents without voltage de-rating. The input voltage ripple will primarily depend on the input capacitor’s ESR. The peak input current is equal to the peak inductor current, so:

$$\Delta V_{IN} = I_{L(pk)} \times C_{ESR} \quad \text{Eq. 14}$$

The input capacitor must be rated for the input current ripple. The RMS value of input capacitor current is determined at the maximum output current. Assuming the peak-to-peak inductor current ripple is low:

$$I_{CIN(RMS)} \approx I_{OUT(MAX)} \times \sqrt{D \times (1-D)} \quad \text{Eq. 15}$$

The power dissipated in the input capacitor is:

$$P_{DISS(CIN)} = I_{CIN(RMS)}^2 \times C_{ESR} \quad \text{Eq. 16}$$

Ripple Injection
The $V_{FB}$ ripple required for proper operation of the MIC28510 $g_{m}$ amplifier and error comparator is 20mV to 100mV. However, the output voltage ripple is generally designed as 1% to 2% of the output voltage. For a low output voltage, such as a 1V, the output voltage ripple is only 10mV to 20mV, and the feedback voltage ripple is less than 20mV. If the feedback voltage ripple is so small that the $g_{m}$ amplifier and error comparator can’t sense it, then the MIC28510 will lose control and the output voltage is not regulated. In order to have some amount of $V_{FB}$ ripple, a ripple injection method is applied for low output voltage ripple applications.

The applications are divided into three situations according to the amount of the feedback voltage ripple:

1) Enough ripple at the feedback voltage due to the large ESR of the output capacitors.

As shown in Figure 7a, the converter is stable without any ripple injection. The feedback voltage ripple is:

$$\Delta V_{FB(pp)} = \frac{R_2}{R_1 + R_2} \times ESR \times \Delta I_{L(pp)} \quad \text{Eq. 17}$$

where $\Delta I_{L(pp)}$ is the peak-to-peak value of the inductor current ripple.

2) Inadequate ripple at the feedback voltage due to the small ESR of the output capacitors.

The output voltage ripple is fed into the FB pin through a feedforward capacitor $C_{FF}$ in this situation, as shown in Figure 7b. The typical $C_{FF}$ value is between 1nF and 22nF.

With the feedforward capacitor, the feedback voltage ripple is very close to the output voltage ripple:

$$\Delta V_{FB(pp)} \approx ESR \times \Delta I_{L(pp)} \quad \text{Eq. 18}$$

3) Virtually no ripple at the FB pin voltage due to the very low ESR of the output capacitors.
In this situation, the output voltage ripple is less than 20mV. Therefore, additional ripple is injected into the FB pin from the switching node SW via a resistor $R_{INJ}$ and a capacitor $C_{INJ}$, as shown in Figure 7c.

The injected ripple is:

$$\Delta V_{FB(PP)} = V_{IN} \times K_{DIV} \times D \times (1-D) \times \frac{1}{f_{SW} \times \tau}$$  \hspace{1cm} \text{Eq. 19}$$

$$K_{DIV} = \frac{R1/R2}{R_{INJ} + R1/R2}$$  \hspace{1cm} \text{Eq. 20}$$

where:

- $V_{IN}$ = Power stage input voltage
- $D$ = Duty cycle
- $f_{SW}$ = Switching frequency
- $\tau = (R1/R2/R_{INJ}) \times C_{FF}$

In Equations 19 and 20, it is assumed that the time constant associated with $C_{FF}$ must be much greater than the switching period:

$$\frac{1}{f_{SW} \times \tau} = \frac{T}{\tau} \ll 1$$  \hspace{1cm} \text{Eq. 21}$$

If the voltage divider resistors R1 and R2 are in the kΩ range, a $C_{FF}$ of 1nF to 22nF can easily satisfy the large time constant requirements. Also, a 100nF injection capacitor $C_{INJ}$ is used in order to be considered as short for a wide range of the frequencies.

The process of sizing the ripple injection resistor and capacitors is:

**Step 1.** Select $C_{FF}$ to feed all output ripples into the feedback pin and make sure the large time constant assumption is satisfied. Typical choice of $C_{FF}$ is 1nF to 22nF if R1 and R2 are in kΩ range.

**Step 2.** Select $R_{INJ}$ according to the expected feedback voltage ripple using Equation 22:

$$k_{DIV} = \frac{\Delta V_{FB(PP)}}{V_{IN}} \times \frac{f_{SW} \times T}{D \times (1-D)}$$  \hspace{1cm} \text{Eq. 22}$$

Then the value of $R_{INJ}$ is obtained as:

$$R_{INJ} = (R1/R2) \times \left(\frac{1}{k_{DIV}} - 1\right)$$  \hspace{1cm} \text{Eq. 23}$$

**Step 3.** Select $C_{INJ}$ as 100nF, which could be considered as short for a wide range of the frequencies.

**Setting Output Voltage**

The MIC28510 requires two resistors to set the output voltage as shown in Figure 8.

The process of sizing the ripple injection resistor and capacitors is:

**Step 1.** Select $C_{FF}$ to feed all output ripples into the feedback pin and make sure the large time constant assumption is satisfied. Typical choice of $C_{FF}$ is 1nF to 22nF if R1 and R2 are in kΩ range.

**Step 2.** Select $R_{INJ}$ according to the expected feedback voltage ripple using Equation 22:

$$k_{DIV} = \frac{\Delta V_{FB(PP)}}{V_{IN}} \times \frac{f_{SW} \times T}{D \times (1-D)}$$  \hspace{1cm} \text{Eq. 22}$$

Then the value of $R_{INJ}$ is obtained as:

$$R_{INJ} = (R1/R2) \times \left(\frac{1}{k_{DIV}} - 1\right)$$  \hspace{1cm} \text{Eq. 23}$$

**Step 3.** Select $C_{INJ}$ as 100nF, which could be considered as short for a wide range of the frequencies.

**Setting Output Voltage**

The MIC28510 requires two resistors to set the output voltage as shown in Figure 8.
The output voltage is determined by Equation 24:

\[ V_O = V_{FB} \times \left(1 + \frac{R1}{R2}\right) \quad \text{Eq. 24} \]

where, \( V_{FB} = 0.8\, \text{V} \). A typical value of \( R1 \) can be between 3k\( \Omega \) and 10k\( \Omega \). If \( R1 \) is too large, it may allow noise to be introduced into the voltage feedback loop. If \( R1 \) is too small, it will decrease the efficiency of the power supply, especially at light loads. Once \( R1 \) is selected, \( R2 \) can be calculated using:

\[ R2 = \frac{V_{FB} \times R1}{V_{OUT} - V_{FB}} \quad \text{Eq. 25} \]

The Figure 9 shows the typical input output relationship. The typical operating point should fall under the non-grey part of the graph shown in Figure 9. This should be used in conjunction with the recommended component values indicated in Table 1 and Bill of Materials Table.

Table 1. Recommended Component values

The inverting input voltage \( V_{INJ} \) is clamped to 1.2V. As the injected ripple increases, the swing of \( V_{INJ} \) will be clamped. The clamped \( V_{INJ} \) reduces the line regulation because it is reflected back as a DC error on the FB terminal.

### Thermal Measurements

Measuring the IC’s case temperature is recommended to ensure it is within its operating limits. Although this might seem like a very elementary task, it is easy to get erroneous results. The most common mistake is to use the standard thermal couple that comes with a thermal meter. This thermal couple wire gauge is large, typically 22 gauge, and behaves like a heatsink, resulting in a lower case measurement.

Two methods of temperature measurement are using a smaller thermal couple wire or an infrared thermometer. If a thermal couple wire is used, it must be constructed of 36 gauge wire or higher (smaller wire size) to minimize the wire heat–sinking effect. In addition, the thermal couple tip must be covered in either thermal grease or thermal glue to make sure that the thermal couple junction is making good contact with the case of the IC. Omega brand thermal couple (5SC–TT–K–36–36) is adequate for most applications.

Wherever possible, an infrared thermometer is recommended. The measurement spot size of most infrared thermometers is too large for an accurate reading on a small form factor ICs. However, an IR thermometer from Optris has a 1mm spot size, which makes it a good choice for measuring the hottest point on the case. An optional stand makes it easy to hold the beam on the IC for long periods of time.
PCB Layout Guidelines

Warning!!! To minimize EMI and output noise, follow these layout recommendations.

PCB Layout is critical to achieve reliable, stable and efficient performance. A ground plane is required to control EMI and minimize the inductance in power, signal and return paths. Thickness of the copper planes is also important in terms of dissipating heat. The 2 oz copper thickness is adequate from thermal point of view and also thick copper plane helps in terms of noise immunity. Keep in mind thinner planes can be easily penetrated by noise.

The following guidelines should be followed to insure proper operation of the MIC28510 converter.

IC
- The 2.2µF ceramic capacitor, which is connected to the VDD pin, must be located right at the IC. The VDD pin is very noise sensitive and placement of the capacitor is very critical. Use wide traces to connect to the VDD and PGND pins.
- The signal ground pin (SGND) must be connected directly to the ground planes. The SGND and PGND connection should be done at a single point near the IC. Do not route the SGND pin to the PGND Pad on the top layer.
- Place the IC close to the point–of–load (POL).
- Use fat traces to route the input and output power lines.
- Signal and power grounds should be kept separate and connected at only one location.

Input Capacitor
- Place the input capacitor next to the power pins.
- Place the input capacitors on the same side of the board and as close to the IC as possible.
- Keep both the PVIN pin and PGND connections short.
- Place several vias to the ground plane close to the input capacitor ground terminal.
- Use either X7R or X5R dielectric input capacitors. Do not use Y5V or Z5U type capacitors.
- Do not replace the ceramic input capacitor with any other type of capacitor. Any type of capacitor can be placed in parallel with the input capacitor.
- If a Tantalum input capacitor is placed in parallel with the input capacitor, it must be recommended for switching regulator applications and the operating voltage must be derated by 50%.

Output Capacitor
- Use a wide trace to connect the output capacitor ground terminal to the input capacitor ground terminal.
- Phase margin will change as the output capacitor value and ESR changes. Contact the factory if the output capacitor is different from what is shown in the BOM.
- The feedback trace should be separate from the power trace and connected as close as possible to the output capacitor. Sensing a long high current load trace can degrade the DC load regulation.

RC Snubber
- Place the RC snubber on either side of the board and as close to the SW pin as possible.

- In “Hot–Plug” applications, a Tantalum or Electrolytic bypass capacitor must be used to limit the over-voltage spike seen on the input supply with power is suddenly applied.

Inductor
- Keep the inductor connection to the switch node (SW) short.
- Do not route any digital lines underneath or close to the inductor.
- Keep the switch node (SW) away from the feedback (FB) pin.
- The CS pin should be connected directly to the SW pin to accurately sense the voltage across the low–side MOSFET.
- To minimize noise, place a ground plane underneath the inductor.
- The inductor can be placed on the opposite side of the PCB with respect to the IC. It does not matter whether the IC or inductor is on the top or bottom as long as there is enough air flow to keep the power components within their temperature limits. The input and output capacitors must be placed on the same side of the board as the IC.

- Place the inductor connection to the switch node (SW) short.

PCB Layout Recommendations (Continued)

Figure 13. MIC28510 Evaluation Board Mid–Layer 2

Figure 14. MIC28510 Evaluation Board Bottom Layer
Recommended Land Pattern

Red circle indicates Thermal Via. Size and must be connected to GND plane for maximum thermal performance.

Green rectangle (with shaded area) indicates Solder Stencil Opening on exposed pad area.

Blue and Magenta colored pads indicate different potential. DO NOT connect to GND plane.
