INTRODUCTION

Target Audience
This application note is intended for hardware and firmware design engineers who need to accurately measure Type-K Thermocouple voltage and convert it to degree Celsius (°C).

Goals
• Accurately measure Type-K Thermocouple
  Electromotive Force (EMF)
• Provide Low-Cost and accurate thermocouple solution

Description
This application note shows how to use a difference amplifier system to measure EMF voltage at the cold junction of thermocouple in order to accurately measure temperature at the hot junction. This can be done by using the MCP6V01 auto-zeroed op amp because of its extremely low input offset voltage ($V_{OS}$) and very high common mode rejection ratio (CMRR). This solution minimizes cost by using resources internal to the PIC18F2550, such as 10-bit ADC and 4-bit adjustable reference, to achieve less than 0.1°C resolution from a measurement range of -100°C to 1000°C.

Related Reference Design Board
The measurements for this application note were made on the MCP6V01 Thermocouple Auto-Zeroed Reference Design Board which is discussed in the user’s guide (DS1738)[9]. This board is further described by:
• Order Number: MCP6V01RD-TCPL
• Assembly Number: 114-00169

THERMOCOUPLE OVERVIEW
Thermocouples are constructed of two dissimilar metals such as Chromel and Alumel (Type-K). The two dissimilar metals are bonded together on one end of the wires with a weld bead, or Hot Junction. The junction point is the temperature sensor. Temperature difference between the Hot Junction and the open junction, Cold Junction, generates measurable voltage between the two terminals of the open junction. This voltage is commonly called the Electromotive Force (EMF) voltage, or Seebeck Effect. This EMF voltage does not require excitation current or voltage. If the difference in temperature between the open and closed end of the Thermocouple wires increases, then the EMF voltage increases proportionally.

The Type-K thermocouple used in the circuit is from OMEGA with part number 5SRTC-TT-K-24-36. The EMF voltage and temperature range of Type-K thermocouple are shown in Figure 1. The voltage shown is referenced to 0°C.

![EMF Voltage vs. Temperature](image)

From Figure 1, it can be summarized that the EMF voltage has relatively small magnitude (millivolts). Consequently, the signal conditioning portion of the electronics requires an analog gain stage. In addition, the signal conditioning circuit must have absolute reference voltage in order to measure temperature with absolute accuracy.
SYSTEM BLOCK DIAGRAM

Figure 2 shows the system block diagram of the solution. The difference amplifier uses MCP6V01 auto-zeroed op amp to amplify the thermocouple’s EMF voltage.

The CVREF is an internal comparator voltage reference of PIC18F2550, which is a 16-tap resistor ladder network that provides a selectable reference voltage. It has low accuracy and high variable output resistance. The buffer amplifier eliminates the output impedance loading effect and produces the voltage $V_{SHIFT}$ that shifts the $V_{OUT1}$.

The $V_{SHIFT}$ is brought back into the PIC18F2550, sampled and calibrated by the internal ADC, then used to adjust measured $V_{OUT1}$, so that the temperature range is segmented into 16 smaller ranges. This gives a greater range (-100°C to +1000°C) and better accuracy.

The MCP1541 provides a reference voltage of 4.1V which references the PIC18F2550’s internal 10-bit ADC. The 2nd order RC low-pass filter reduces noise and aliasing at the ADC input.

The MCP9800 senses temperature at the thermocouple connector, or cold-junction. It should be located as close as possible to the connector on the PCB. This measurement is used to perform cold junction compensation for the thermocouple measurement.

The Thermal Management Software is used to perform data acquisition to show the real-time temperature data.

**FIGURE 2:** System Block Diagram.
HARDWARE CIRCUITS

Voltage Sensors With Common Mode Noise

Any remote voltage sensor with differential output is usually subject of high common-mode noise. An example would be a temperature sensor for an engine, such as a thermocouple sensor.

**EQUATION 1:**

\[ V_{CM} = \frac{V_1 + V_2}{2}, \quad V_{DM} = V_1 - V_2 \]

Where:
- \( V_{CM} \) = Common Mode Voltage
- \( V_{DM} \) = Difference Mode Voltage
- \( V_1, V_2 \) = Differential Outputs of Remote Voltage Sensor

**Figure 3** shows voltage sensors with high common mode noise.

Common mode noise is reduced by shielding, PCB layout, and using a difference or instrumentation amplifier. In this application note, we will focus on using difference amplifier to reduce the common mode noise.

**Difference Amplifier**

**Figure 5** shows a difference amplifier using an op amp. It presents an impedance of \( R_1 \) to each end of the sensor \( (V_1 \text{ and } V_2) \) and amplifies the input difference voltage \( (V_1 - V_2) \).

An ideal difference amplifier gives an output as:

**EQUATION 2:**

\[ V_{OUT} = G_{DM} \times (V_1 - V_2) \]

\[ G_{DM} = \frac{R_2}{R_1} \]

Where:
- \( G_{DM} \) = Difference Mode Gain

**Advantages:**
- Resistive isolation from the source
- Large input voltage range is possible
- Rejects common mode noise
- Simplicity

**Disadvantages:**
- Resistive loading of the source
- Input stage distortion

**Figure 4** shows voltage sensor with low common mode noise.

**Figure 5:** Difference Amplifier
Equation 3 gives a more practical result for the difference amplifier.

**EQUATION 3:**

\[
V_{OUT} = G_{DM} \times (V_1 - V_2) + G_{CM} \times \left(\frac{V_1 + V_2}{2}\right)
\]

\[
G_{DM} = \frac{R_2}{R_1} \quad G_{CM} = \frac{G_{DM}}{CMRR_{DIFF}}
\]

Where:
- \( G_{DM} \) = Difference Mode Voltage
- \( G_{CM} \) = Common Mode Voltage
- \( CMRR_{DIFF} \) = Common Mode Rejection Ratio of Difference Amplifier

From the above equation, it can be summarized that a practical difference amplifier amplifies the difference mode voltage by \( G_{DM} \) and the common mode voltage by \( G_{CM} \).

The CMRR_{DIFF} is given by:

**EQUATION 4:**

\[
CMRR_{DIFF} = \frac{1}{CMRR_{OP}} + 2 \times TOL_R
\]

Where:
- \( TOL_R \) = Resistors’ Tolerance
- \( CMRR_{OP} \) = Common Mode Rejection Ratio of Operational Amplifier

Notice that a difference amplifier with lower \( TOL_R \) and higher \( CMRR_{OP} \) will have the higher CMRR_{DIFF}.

If the op amp’s CMRR (CMRR_{OP}) is given in V/V (e.g., 80 dB is converted to 10,000 V/V), and the resistor tolerance (TOL_R) is given in absolute terms (e.g., 0.1% becomes 0.001), then the difference amplifier’s CMRR (CMRR_{DIFF}) will be in V/V (for the example already given, 476 V/V = 54 dB).

Equation 3 shows that as CMRR_{DIFF} increases, \( G_{CM} \) becomes smaller. For a perfectly symmetrical difference amplifier, as CMRR_{DIFF} approaches infinity, \( G_{CM} \) approaches zero.

**Analog Sensor Conditioning Circuit**

Figure 6 shows the analog sensor conditioning circuit. It includes three building blocks:
- Buffer Amplifier
- Difference Amplifier
- 2nd Order Low-Pass Filter

**BUFFER AMPLIFIER**
- MCP6001 standard op amp used as unity gain buffer
- Provides a low impedance adjustable reference voltage

**DIFFERENCE AMPLIFIER**
- \( V_{DD} = 5.0V, V_{SS} = 0V \)
- Uses a MCP6V01 auto-zeroed op amp (U5)
- Two 0.1% tolerance gain resistors (R8 and R11)
- Two 0.1% tolerance input resistors for shifting \( V_{OUT1} \) (R9 and R10)
- Two 0.1% tolerance input resistors for the thermocouple output (R6 and R7)

The difference amplifier is powered in single supply configuration and \( V_{DD} \) should have a local bypass capacitor (i.e., 0.01 \( \mu F \) to 0.1 \( \mu F \)). \( V_{OUT1} \) must be kept within the ADC’s allowed voltage range, which is scaled by the gain of MCP6V01. The low tolerance gain setting resistors are matched to provide symmetry for good common mode rejection.

The MCP6V01 auto-zeroed op amp less than 2 \( \mu V \) input offset voltage and high common-mode rejection ratio makes it ideal for thermocouple sensing applications.
The transfer function set by the difference amplifier is:

**EQUATION 6:**

\[ V_{OUT1} = G_1 \times V_{TH} + G_2 \times (0 - V_{SHIFT}) + V_{REF} \]
\[ = G_1 \times V_{TH} - G_2 \times V_{SHIFT} + V_{REF} \]

Where:
- \( V_{TH} = V_P - V_M \); EMF Voltage from Thermocouple
- \( V_{REF} = 4.1V \); Reference Voltage
- \( V_{SHIFT} = C \times V_{REF} \)
- \( V_{OUT1} = \) Output Voltage of Difference Amplifier
- \( G_1 = \frac{R_{11}}{R_7} = \frac{R_8}{R_6} = 1000 \) V/V
- \( G_2 = \frac{R_{11}}{R_{10}} = \frac{R_8}{R_9} = 17.86 \) V/V

2\(^{nd}\) ORDER RC LOW-PASS FILTER
- Fast enough to quick changes in temperature
- Double pole for anti-aliasing and removing high-frequency noise
- No DC offset and simple architecture

The pole set by the low-pass filter is:

**EQUATION 7:**

\[ f_P = \frac{1}{2\pi R_{12} C_6} = \frac{1}{2\pi R_{13} C_7} = 3.19Hz \]

*FIGURE 6: Analog Sensing Circuit Diagram.*
**VSHIFT Operation Description**

PIC18F2550’S COMPARATOR VOLTAGE REFERENCE BLOCK DIAGRAM

The comparator voltage reference is a 16-tap resistor ladder network that provides a selectable reference voltage. Although its primary purpose is to provide a reference for the analog comparators, it may also be used independently of them. A block diagram of the module is shown in Figure 7. The resistor ladder is segmented to provide two ranges of CVREF values and has a power-down function to conserve power when the reference is not being used. The module’s supply reference can be provided from either device VDD/VSS or an external voltage reference.

In this application note, CVRSS = 1 is set for VREF+ and CVRSS = 0 is set for VREF-. The MCP1541 provides an absolute reference voltage 4.1V. (VREF+ = 4.1V and VREF- = 0V).

![PIC18F2550 Comparator Voltage Reference Block Diagram](image)

**FIGURE 7:** PIC18F2550 Comparator Voltage Reference Block Diagram.
V\textsubscript{SHIFT} OPERATION CONCEPTUAL DIAGRAM

Figure 8 shows the V\textsubscript{SHIFT} operation conceptual diagram. V\textsubscript{SHIFT} is also connected to the PIC18F2550 ADC channels along with V\textsubscript{OUT2}, which is used to calculate Thermocouple EMF voltage. The 10-bit ADC and the 4-bit adjustable reference voltage provide a 14-bit measurement resolution. The MCP1541 provides an absolute reference to the ADC and difference amplifier circuit.

- 14-bit Resolution, 10-bit ADC:
  - PIC18F2550's CV\textsubscript{REF} (4-bit Adjustable Reference Voltage)
  - PIC18F2550's internal 10-bit ADC
  - The firmware automatically searches for correct CV\textsubscript{REF} level

This solution minimizes cost by using resources internal to the PIC to achieve high accuracy and high resolution thermocouple solution. This solution eliminates the need for a high end and costly instrumentation system to measure temperature using thermocouple. Further savings could be achieved by using a voltage reference internal to the PIC instead of the external MCP1541.

**FIGURE 8:** V\textsubscript{SHIFT} Operation Conceptual Diagram.
Automatic Reference Voltage Search

Figure 9 shows a screen capture from an oscilloscope while the PIC18F2550 searches a reference voltage $V_{\text{SHIFT}}$. Channel 1 (yellow trace) is the MCP6V01 output $V_{\text{OUT1}}$ and Channel 2 is $V_{\text{SHIFT}}$. $V_{\text{SHIFT}}$ is adjusted until the output is scaled within a voltage range of 0.2V to 4V, as shown in Table 1. The search is sequenced by first setting CVREF levels 0, 15, 1, 14, 2, 13, ..., 6, 9, and 7. The voltage at level 7 sets the output to equal approximately 0.7V. Then, EMF is calculated by measuring $V_{\text{SHIFT}}$ and $V_{\text{OUT2}}$.

FIRMWARE AND SOFTWARE

Firmware

The firmware uses the PIC18F2550 USB PIC® Microcontroller to compute Thermocouple temperature and transfer temperature data to PC via the USB interface. The firmware has two major functions, maintain USB interface with PC and measure/compute temperature.

The firmware uses USB HID interface and does not require PC side driver software. Once the USB is connected to a PC the USB module is initialized, and the Thermocouple temperature conversion is started upon a successful USB initialization.

The Thermocouple measurement routine starts by measuring the thermocouple output voltage from the MCP6V01. If the output voltage is out of range as shown in the Table 1 then the reference voltage is adjusted automatically as shown in Figure 9. Once the corresponding VSHIFT value is determined, both VOUT2 and VSHIFT are digitized using the 10bit ADC. From these voltages, the Thermocouple EMF is calculated. The EMF voltage is converted to temperature in degree Celcius (°C) using the 9th order equation provided by ITS-90 standard (www.nist.org). The temperature value is cold-junction compensated using the MCP9800 temperature sensor.

EQUATION 8: EMF CALCULATION

\[ EMF = (V_{OUT2} + V_{SHIFT} \cdot Gain - V_{REF}) \]

Where:
- EMF = Thermocouple voltage (mV)
- VOUT2 = MCP6V01 Filtered Output (V)
- VSHIFT = Adjustable reference voltage (V)
- Gain = Difference Amplifier Gain (R8/R9)
- VREF = Absolute reference voltage, MCP1541 output (V)

EQUATION 9: COLD JUNCTION COMPENSATION

\[ T = T_{CJ} - T_{HJ} \]

Where:
- T = Absolute Thermocouple temperature (°C)
- TCJ = Cold-Junction temperature, MCP9800 output (°C)
- THJ = Hot-Junction temperature or Thermocouple temperature from ITS-90 standard (°C)

The temperature data is stored in memory in IEEE Standard for Floating-Point Arithmetic (IEEE 754). When a temperature data is requested from the PC the floating point data is converted to Binary Code Decimal (BCD) and each byte is loaded in the USB data transfer buffer. Along with the temperature data, VOUT2, VSHIFT and the cold-junction temperature are loaded. The PC Graphical User Interface (GUI) converts the BCD data to floating point number which represents temperature. The temperature data is displayed and plotted on the graphical display. Additionally, the GUI displays EMF voltage, thermocouple output and cold junction temperature.

FIGURE 10: Top Level Flow Chart.
Thermal Management Software GUI

The GUI is a measurement tool which enables user to see the changes in temperature graphically by displaying the Thermocouple raw output data along with linearized temperature data. It also enables user to calibrate the system.

Temperature can also be measured over an extended period of time by clicking the Start Acquisition button or Play button. The measurement interval is controlled by the software timer. When the timer ticks a command is sent to the hardware to acquire temperature data then the firmware transfers the last successfully converted temperature data.

Additionally, user can calibrate the Thermocouple sensor by using the calibration option from the GUI. This feature can be enabled by clicking on the Enable Calibration check box. Once enabled, user can type in the thermocouple calibration temperature and click the Calibrate! button. When calibrated, the temperature difference between the thermocouple and calibration temperature is stored in the PICmicro EEPROM. The difference is also shown in the “Calibration Offset” display of the GUI. Once calibrated, the offset is subtracted from temperature measurements. In addition, clicking the Reset button clears the calibration offset value to 0 (the EEPROM content is set to 0).

FIGURE 11: Graphical User Interface.
SUMMARY
This application note shows hardware and firmware design engineers how to use a PICmicro® Microcontroller and a difference amplifier system to measure Type-K Thermocouple voltage to accurately measure temperature from -100°C to 1000°C using a 10-bit ADC and 4-bit adjustable reference voltage.
